SECTION I MEASUREMENT

Chapter 1: Measurement

- SI Units
- Errors and Uncertainties

- Scalars and Vectors

a. Recall the following base quantities and their units; mass (kg), length (m), time (s), current (A), temperature (K), amount of substance (mol).

Base Quantities	SI Units		
Base quantities	Name	Symbol	
Length	metre	m	
Mass	kilogram	kg	
Time	second	S	
Amount of substance	mole	mol	
Temperature	Kelvin	K	
Current	ampere	A	
Luminous intensity	candela	cd	

b. Express derived units as products or quotients of the base units and use the named units listed in 'Summary of Key Quantities, Symbols and Units' as appropriate.

A derived unit can be expressed in terms of products or quotients of base units.

Derived Quantities	Equation	Derived Units
Area (A)	$A = L^2$	m ²
Volume (V)	$V = L^3$	m ³
Density (ρ)	$\rho = \frac{m}{V}$	$\frac{\mathrm{kg}}{\mathrm{m}^3} = \mathrm{kg} \mathrm{m}^{-3}$
Velocity (v)	$v = \frac{L}{t}$	$\frac{m}{s} = m s^{-1}$
Acceleration (a)	$a = \frac{\Delta V}{t}$	$\frac{m s^{-1}}{s} = m s^{-2}$
Momentum (p)	p = m x v	$(kg)(m s^{-1}) = kg m s^{-1}$

Derived Quantities	Equation		d Unit	Derived Units
Derived Quantities	Equation	Special Name	Symbol	Derived Offics
Force (F)	$F = \frac{\Delta p}{t}$	Newton	Ν	$\frac{\text{kg m s}^{-1}}{\text{s}} = \text{kg m s}^{-2}$
Pressure (p)	$p = \frac{F}{A}$	Pascal	Ра	$\frac{\text{kg m s}^{-2}}{\text{m}^2} = \text{kg m}^{-1} \text{ s}^{-2}$
Energy (E)	E = F x d	joule	J	$(kg m s^{-2})(m) = kg m^2 s^{-2}$
Power (P)	$P = \frac{E}{t}$	watt	W	$\frac{\text{kg m}^2 \text{ s}^{-2}}{\text{s}} = \text{kg m}^2 \text{ s}^{-3}$
Frequency (f)	$f = \frac{1}{t}$	hertz	Hz	$\frac{1}{s} = s^{-1}$
Charge (Q)	Q = I x t	coulomb	С	As
Potential Difference (V)	$V = \frac{E}{Q}$	volt	V	$\frac{\text{kg m}^2 \text{ s}^{-2}}{\text{A s}} = \text{kg m}^2 \text{ s}^{-3} \text{ A}^{-1}$
Resistance (R)	$R = \frac{V}{I}$	ohm	Ω	$\frac{\text{kg m}^2 \text{ s}^{-3} \text{ A}^{-1}}{\text{A}} = \text{kg m}^2 \text{ s}^{-3} \text{ A}^{-2}$

SECTION II NEWTONIAN MECHANICS

Cha	pter 2: Kinematic - Rectilinear M	otion
a.	- Non-linear M Define displace	otion ment, speed, velocity and acceleration.
	Distance:	Total length covered irrespective of the direction of motion.
	Displacement:	Distance moved in a certain direction
	Speed:	Distance travelled per unit time.
	-	
	Velocity:	is defined as the rate of change of displacement, or, displacement per unit time { NOT : displacement <u>over</u> time, nor, displacement <u>per second</u> , nor, rate of change of displacement per unit time}
	Acceleration:	is defined as the rate of change of velocity.
b.	Use graphical acceleration.	methods to represent distance travelled, displacement, speed, velocity and
	Self-explanatory	
C.	Find displaceme	ent from the area under a velocity-time graph.
	The area under a	a velocity-time graph is the <u>change</u> in displacement.
d.	Use the slope o	f a displacement-time graph to find velocity.
	The gradient of a	displacement-time graph is the {instantaneous} velocity.
e.	Use the slope o	f a velocity-time graph to find acceleration.
	The gradient of a	velocity-time graph is the acceleration.
f.		ne definitions of velocity and acceleration, equations that represent uniformly
g.	Solve problems	tion in a straight line. s using equations which represent uniformly accelerated motion in a straight line, otion of bodies falling in a uniform gravitational field without acceleration.
	1. $v = u + a$ 2. $s = \frac{1}{2} (u$ 3. $v^2 = u^2$ 4. $s = ut$	
		apply only if the motion takes place <u>along a straight line</u> and the <u>acceleration is constar</u> ir resistance must be negligible.}
h.	Describe qualita	atively the motion of bodies falling in a uniform gravitational field with air resistance.
	Consider a body	moving in a uniform gravitational field under 2 different conditions:
	<u>A WITHO</u>	UT AIR RESISTANCE
		$ \begin{array}{c} 2 \\ \hline \\ 3 \end{array} \\ \end{array} \\ t \end{array} \\ t \end{array} \\ \begin{array}{c} 2 \\ t \\ \hline \\ 0 \end{array} \\ \end{array} \\ \begin{array}{c} 2 \\ t \\ \hline \\ 0 \end{array} \\ \end{array} \\ \begin{array}{c} 2 \\ t \\ \hline \\ 0 \end{array} \\ \begin{array}{c} 2 \\ t \\ \hline \\ 0 \end{array} \\ \end{array} \\ \begin{array}{c} 2 \\ t \\ \hline \\ 0 \end{array} \\ \begin{array}{c} 2 \\ t \\ \hline \\ 0 \end{array} \\ \begin{array}{c} 2 \\ t \\ \hline \\ 0 \end{array} \\ \begin{array}{c} 2 \\ t \\ \hline \\ 0 \end{array} \\ \begin{array}{c} 2 \\ t \\ \hline \\ 0 \end{array} \\ \begin{array}{c} 2 \\ t \\ \hline \\ 0 \end{array} \\ \begin{array}{c} 2 \\ t \\ \hline \\ 0 \end{array} \\ \begin{array}{c} 2 \\ t \\ \hline \\ 0 \end{array} \\ \begin{array}{c} 2 \\ t \\ \hline \\ 0 \end{array} \\ \begin{array}{c} 2 \\ t \\ 0 \end{array} \\ \end{array} \\ \begin{array}{c} 2 \\ t \\ 0 \end{array} \\ \end{array} \\ \begin{array}{c} 2 \\ t \\ 0 \end{array} \\ \end{array} \\ \begin{array}{c} 2 \\ t \\ 0 \end{array} \\ \end{array} \\ \begin{array}{c} 2 \\ t \\ 0 \end{array} \\ \end{array} \\ \begin{array}{c} 2 \\ t \\ 0 \end{array} \\ \end{array} \\ \begin{array}{c} 2 \\ t \\ 0 \end{array} \\ \end{array} \\ \end{array} \\ \begin{array}{c} 2 \\ t \\ \end{array} \\ \end{array} \\ \end{array} \\ \begin{array}{c} 2 \\ t \\ \end{array} \\ \end{array} \\ \end{array} \\ \end{array} \\ \begin{array}{c} 2 \\ t \\ \end{array} \\ \end{array}$
	the weight of the	<u>ible air resistance</u> , whether the body is moving up, or at the highest point or moving down, body, W, is the <u>only force</u> acting on it, causing it to experience a <u>constant acceleration</u> . <u>nt</u> of the v-t graph is <u>constant throughout</u> its rise and fall. The body is said to undergo <i>free</i>

9

Cha	pter 3: Dynamics - Newton's laws of motion
	- Linear momentum and its conservation
а.	State each of Newton's laws of motion.
	Newton's First Law Every body continues in a state of rest or uniform motion in a straight line unless a net (external) force acts on it.
	<u>Newton's Second Law</u> The rate of change of momentum of a body is directly proportional to the net force acting on the body, and the <u>momentum change takes place in the direction of the net force.</u>
	<u>Newton's Third Law</u> When object X exerts a force on object Y, object Y exerts a force <i>of the same type</i> that is equal in magnitude and opposite in direction on object X.
	The two forces ALWAYS act on different objects and they form an action-reaction pair.
b.	Show an understanding that mass is the property of a body which resists change in motion.
	Mass: is a measure of the amount of matter in a body, & is the property of a body which resists change in motion.
C.	Describe and use the concept of weight as the effect of a gravitational field on a mass.
	Weight: is the force of gravitational attraction (exerted by the Earth) on a body.
d.	Define linear momentum and impulse.
	Linear momentum of a body is defined as the product of its mass and velocity ie $\mathbf{p} = \mathbf{m} \mathbf{v}$
	Impulse of a force / is defined as the product of the force and the time Δt during which it acts
	ie I = F x Δt {for force which is <u>const</u> over the duration Δt }
	For a variable force, the impulse = Area under the F-t graph { JFdt; may need to "count squares"}
	Impulse is <u>equal in magnitude</u> to the change in momentum of the body acted on by the force. Hence the change in momentum of the body is equal in mag to the area under a (net) force-time graph. { <u>Incorrect</u> to <u>define</u> impulse as <i>change in momentum</i> }
e.	Define force as rate of change of momentum.
	Force is defined as the rate of change of momentum, ie $F = \frac{m(v - u)}{t} = ma$ or $F = v \frac{dm}{dt}$
	The {one} Newton is defined as the force needed to accelerate a mass of 1 kg by 1 m s ⁻² .
f.	Recall and solve problems using the relationship $F = ma$ appreciating that force and acceleration are always in the same direction.
	Self-explanatory
g.	State the principle of conservation of momentum.
	Principle of Conservation of Linear Momentum: When objects of a system interact, their total momentum before and after interaction are equal if no net (external) force acts on the system.
	or, The total momentum of an <u>isolated</u> system is constant ie $m_1 u_1 + m_2 u_2 = m_1 v_1 + m_2 v_2$ if net $F = 0$ {for all collisions }
	NB: Total momentum DURING the interaction/collision is also conserved.
h.	Apply the principle of conservation of momentum to solve problems including elastic and inelastic

	interactions between two bodie required.)	es in one dimension. (Knowledge of coefficient of restitution is not
	(Perfectly) elastic collision:	Both momentum & kinetic energy of the system are conserved.
	Inelastic collision:	Only momentum is conserved, total kinetic energy is not conserved.
	Perfectly inelastic collision:	Only momentum is conserved, and the particles stick together after collision. (i.e. move with the same velocity.)
i.	Recognise that, for a perfectly is equal to the relative speech o	elastic collision between two bodies, the relative speed of approach f separation.
	For all <i>elastic</i> collisions, u ₁ – u ₂	$= V_2 - V_1$
	ie. relative speed of approach =	relative speed of separation
	or, $\frac{1}{2} m_1 u_1^2 + \frac{1}{2} m_2 u_2^2 = \frac{1}{2}$	$m_1 v_1^2 + \frac{1}{2} m_2 v_2^2$
j.	•	hilst the momentum of a system is always conserved in interactions n kinetic energy usually takes place.
	In inelastic collisions, total energy energy such as sound and heat er	y is conserved but Kinetic Energy may be converted into other forms of nergy.

Cha	pter 4: Forces
	 Types of force Equilibrium of force
	- Centre of gravity
а.	- Turning effects of forces Recall and apply Hooke's Law to new situations or to solve related problems.
a.	
	Within the limit of proportionality, the extension produced in a material is directly proportional to the force/load applied
	ie F = kx
_	Force constant k = force per unit extension (F/x) {N08P3Q6b(ii)}
b.	Deduce the elastic potential energy in a deformed material from the area under a force-extension graph.
	Elastic potential energy/strain energy = Area under the F-x graph {May need to "count the squares"}
	For a material that obeys Hooke's law,
	Elastic Potential Energy, $E = \frac{1}{2} F x = \frac{1}{2} k x^2$
с.	Describe the forces on mass, charge and current in gravitational, electric and magnetic fields, as appropriate.
	Forces on Masses in Gravitational Fields - A region of space in which a <u>mass</u> experiences an (attractive) force due to the presence of <u>another mass</u> .
	Forces on Charge in Electric Fields - A region of space where a <u>charge</u> experiences an (attractive or repulsive) force due to the presence of <u>another charge</u> .
	Forces on Current in Magnetic Fields - Refer to Chapter 15
d.	Solve problems using p = ρgh.
	Hydrostatic Pressure p = ρg h
	{or, pressure difference between 2 points separated by a vertical distance of h }
e. f.	Show an understanding of the origin of the upthrust acting on a body in a fluid. State that an upthrust is provided by the fluid displaced by a submerged or floating object.
	Upthrust: An upward force exerted by a fluid on a submerged or floating object; arises because of the difference in pressure between the upper and lower surfaces of the object.
g.	Calculate the upthrust in terms of the weight of the displaced fluid.
h.	Recall and apply the principle that, for an object floating in equilibrium, the upthrust is equal to the weight of the new object to new situations or to solve related problems.
	Archimedes' Principle: Upthrust = weight of the fluid displaced by submerged object.
	ie Upthrust = Vol _{submerged} × ρ _{fluid} × g
i.	Show a qualitative understanding of frictional forces and viscous forces including air resistance. (No treatment of the coefficients of friction and viscosity is required.)
	 Frictional Forces: The contact force between two surfaces = (friction² + normal reactionn²)^{1/2} The component along the surface of the contact force is called friction. Friction between 2 surfaces always opposes relative motion {or attempted motion}, and Its value varies up to a maximum value {called the static friction}
	Viscous Forces:
	studyguide.pk 13

		oses the motion of an object in a fluid;
		n there is (relative) motion.
	 Magnitude of vis 	scous force increases with the speed of the object
j.	Use a vector triangle to	represent forces in equilibrium.

_	5: Work, Energy and Power		
	Work Energy conversion and conservation		
-	Potential energy and kinetic energy		
a. Sho	Power Show an understanding of the concept of work in terms of the product of a force and displacement		
	the direction of the force. Iculate the work done in a number of situations including the work done by a gas which is		
	panding against a constant external pressure: W = pΔV.		
Wo	ork Done by a force is defined as the product of the force and displacement (of its point of application) in the direction of the force		
	ie W = Fscosθ		
Neg	gative work is said to be done by F if x or its compo. is <u>anti-parallel</u> to F		
	variable force F produces a displacement in the direction of F, the work done is determined from the area der F-x graph. {May need to find area by "counting the squares". }		
	ve examples of energy in different forms, its conversion and conservation, and apply the principle energy conservation to simple examples.		
By F	Principle of Conservation of Energy,		
Wo	ork Done on a system =		
	gain + GPE gain + Thermal Energy generated {ie Work done against friction}		
d. Der	rive, from the equations of motion, the formula $E_k = \frac{1}{2}mv^2$.		
	nsider a rigid object of mass m that is initially at rest. To accelerate it uniformly to a speed v, a constant force F is exerted on it, parallel to its motion over a displacement s.		
Sind	ce F is constant, acceleration is constant,		
The	erefore, using the equation: $v^2 = u^2 + 2 a s$, a s $= \frac{1}{2} (v^2 - u^2)$		
Sind	ce kinetic energy is equal to the work done on the mass to bring it from rest to a speed v,		
The	e kinetic energy, E_{K} = Work done by the force F		
	= F s = m a s		
	$=\frac{1}{2}m(v^2 - u^2)$		
	-		
e. Rec	call and apply the formula $E_k = \frac{1}{2}mv^2$.		
Self	f-explanatory		
	stinguish between gravitational potential energy, electric potential energy and elastic potential ergy.		
forc	avitational potential energy : this arises in a system of <i>masses</i> where there are attractive gravitational ces between them. The gravitational potential energy of an object is the energy it possesses by virtue of position in a gravitational field.		
	stic potential energy : this arises in a system of atoms where there are either attractive or repulsive ort-range inter-atomic forces between them. (From Topic 4, E. P. E. = $\frac{1}{2}$ k x ² .)		
Ele	ctric potential energy: this arises in a system of charges where there are either attractive or repulsive		

	electric forces between them.		
g.	Show an understanding of and use the relationship between force and potential energy in a uniform field to solve problems.		
	The potential energy, U, of a body in a force field {whether gravitational or electric field} is related to the force F it experiences by: $F = -\frac{dU}{dx}$.		
h.	Derive, from the defining equation W = Fs the formula E_p = mgh for potential energy changes near the Earth's surface.		
	Consider an object of mass m being lifted vertically by a force F, without acceleration, from a certain height h_1 to a height h_2 . Since the object moves up at a constant speed, F is equal to m g. The change in potential energy of the mass = Work done by the force F = F s = F h = m g h		
i.	Recall and use the formula E_p = mgh for potential energy changes near the Earth's surface.		
	Self-explanatory		
j.	Show an appreciation for the implications of energy losses in practical devices and use the concept of efficiency to solve problems.		
	Efficiency: The ratio of (useful) output energy of a machine to the input energy.		
	ie = Useful Output Energy × 100 % = Useful Output Power × 100 %		
k.	Define power as work done per unit time and derive power as the product of force and velocity.		
	Power {instantaneous} is defined as the work done per unit time.		
	$P = \frac{\text{Total Work Done}}{\text{Total Time}}$ $= \frac{W}{t}$		
	Since work done $W = F x s$, F x s		
	$P = \frac{F \times s}{t}$ $= F v$		
	 for object moving at <u>const speed</u>: F = Total resistive force {equilibrium condition} for object beginning to <u>accelerate</u>: F = Total resistive force <u>+ ma</u> {N07P1Q10,N88P1Q5} 		

Cha	Chapter 6: Motion in a Circle Kinematics of uniform circular motion		
	- Centripetal acceleration		
a.	- Centripetal force Express angular displacement in radians.		
u.			
	Radian (rad) is the S.I. unit for angle, θ and it can be related to degrees in the following way. In one complete revolution, an object rotates through 360°, or 2π rad.		
	As the object moves through an angle θ , with respect to the centre of rotation, this angle θ is known as the angular displacement .		
b.	Understand and use the concept of angular velocity.		
	Angular velocity (ω) of the object is the rate of change of angular displacement with respect to time.		
	$\omega = \frac{\theta}{t} = \frac{2\pi}{T}$ (for one complete revolution)		
c.	Recall and use $v = r_{0}$.		
	Linear velocity, v, of an object is its instantaneous velocity at any point in its circular path.		
	$v = \frac{\text{arc length}}{\text{time taken}} = \frac{r\theta}{t} = r\omega$		
	Note : (i) The direction of the linear velocity is at a <i>tangent</i> to the circle described at that point. Hence it is sometimes referred to as the <i>tangential velocity</i> .		
	(ii) ω is the same for every point in the rotating object, but the linear velocity <i>v</i> is greater for points further from the axis.		
d.	Describe qualitatively motion in a curved path due to a perpendicular force, and understand the centripetal acceleration in the case of a uniform motion in a circle.		
	A body moving in a circle at a <u>constant speed</u> changes velocity {since its direction changes}. Thus, it <i>always</i> experiences an acceleration, a force and a change in momentum.		
e.	Recall and use centripetal acceleration $a = r\omega^2$, $a = \frac{v^2}{r}$.		
	Centripetal acceleration, $\mathbf{a} = \mathbf{r} \omega^2$ $= \frac{\mathbf{v}^2}{\mathbf{r}}$ {in magnitude}		
f.	Recall and use centripetal force $F = mr\omega^2$, $F = \frac{mv^2}{r}$.		
	Centripetal force is the resultant of all the forces that act on a system in circular motion.		
	{It is not a particular force; "centripetal" means "centre-seeking". Also, when asked to draw a diagram showing all the forces that act on a system in circular motion, it is wrong to include a force that is labelled as "centripetal force". }		
	Centripetal force, F = m r $\omega^2 = \frac{mv^2}{r}$ {in magnitude}		
	A person in a satellite orbiting the Earth experiences " weightlessness " although the gravi field strength at the height is not zero because the person and the satellite would both have the <u>same acceleration</u> ; hence the contact force between man & satellite/ <u>normal reaction on the person is zero {</u> Not because the field strength is negligible.}		

Cha	pter 7: Gravitation		
•	- Gravitational Field		
	 Force between point masses Field of a point mass 		
	- Field near to the surface of the Earth		
	- Gravitational Potential		
а.	A. Show an understanding of the concept of a gravitational field as an example of field of force define gravitational field strength as force per unit mass.		
	Gravitational field strength at a point is defined as the gravitational force per unit mass at that point.		
b.	Recall and use Newton's law of gravitation in the form $F = \frac{GMm}{r^2}$		
	Newton's law of gravitation : The (mutual) gravitational force F between two point masses M and m separated by a distance r is given by		
	$\mathbf{F} = \frac{\mathbf{GMm}}{\mathbf{r}^2}$ where G: Universal gravitational constant		
	or, the gravitational force of between two point masses is proportional to the product of their masses & inversely proportional to the square of their separation.		
с.	Derive, from Newton's law of gravitation and the definition of gravitational field strength, the		
	equation $g = \frac{GM}{r^2}$ for the gravitational field strength of a point mass.		
	Gravitational field strength at a <i>point</i> is the gravitational force per unit mass at that point. It is a vector and its S.I. unit is N kg ⁻¹ .		
	By definition, $g = \frac{F}{m}$		
	By Newton Law of Gravitation, $F = \frac{GMm}{r^2}$		
	Combining, magnitude of $g = \frac{GM}{r^2}$		
	Therefore $\mathbf{g} = \frac{\mathbf{GM}}{\mathbf{r}^2}$, M = Mass of object "creating" the field		
d.	Recall and apply the equation $g = \frac{GM}{r^2}$ for the gravitational field strength of a point mass to new		
	situations or to solve related problems.		
	Example 7D1 Assuming that the Earth is a uniform sphere of radius 6.4 x 10^6 m and mass 6.0 x 10^{24} kg, find the gravitational field strength g at a point		
	(a) <u>on the surface,</u>		
	$g = \frac{GM}{r^2} = (6.67 \times 10^{-11})(6.0 \times 10^{24}) / (6.4 \times 10^6)^2$		
	$= 9.77 \text{ m s}^{-2}$		
	(b) <u>at height 0.50 times the radius of above the Earth's surface.</u>		
	$g = \frac{GM}{r^2} = (6.67 \times 10^{-11})(6.0 \times 10^{24}) / (1.5 \times 6.4 \times 10^6)^2$ = 4.34 m s ⁻²		
	Example 7D2 The acceleration due to gravity at the Earth's surface is 9.80 m s ⁻² . Calculate the acceleration due to gravity on a planet which has the same density but twice the radius of Earth.		

	$g = \frac{GM}{r^2}$	
	9- ····	
	$\frac{4}{3}\pi r_{P}^{3} r_{E}^{2} \rho_{P}$	
	$=\frac{\frac{4}{3}\pi r_{P}{}^{3} r_{E}{}^{2} \rho_{P}}{\frac{4}{3}\pi r_{E}{}^{3} r_{P}{}^{2} \rho_{E}}$	
	3 ^{πr} ε ⁻ r _P -ρ _E	
	= 2	
	\sim	
	Hence $g_P = 2 \times 9.81 = 19.6 \text{ m s}^{-2}$.	
е.	Show an appreciation that on the surface of the Earth g is approximately constant and is called the acceleration of free fall.	
	Assuming that Earth is a uniform sphere of mass M. The magnitude of the gravitational force from Earth on a particle of mass m, located outside Earth a distance r from the centre of the Earth is	
	$F = \frac{GMm}{r^2}$. When a particle is released, it will fall towards the centre of the Earth, as a result of the	
	gravitational force with an acceleration a _g .	
	i.e. , $F_G = ma_g$	
	$a_g = \frac{GM}{r^2}$	
	Hence $a_g = g$	
	Thus gravitational field strength g is also numerically equal to the acceleration of free fall.	
	Example 7E1 A ship is at rest on the Earth's equator. Assuming the earth to be a perfect sphere of radius R and t acceleration due to gravity at the poles is g_0 , express its apparent weight, N, of a body of mass m in term of m, g_0 , R and T (the period of the earth's rotation about its axis, which is one day).	
	Ans: At the North Pole, the gravitational attraction is $F = \frac{GM_Em}{R^2} = mg_0$	
	At the equator,	
	Normal Reaction	
	Force on ship by Earth = Gravitational attraction – centripetal force $N = mg_{o} - mR\omega^{2}$	
	$= mg_{o} - mR \left(\frac{2\pi}{T}\right)^{2}$	
	$= mg_o - m\kappa (\overline{T})^-$	
f.	Define potential at a point as the work done in bringing unit mass from infinity to the point.	
	Gravitational potential at a point is defined as the work done (by an external agent) in bringing a <u>unit</u> mass from infinity to that point (without changing its kinetic energy).	
g.	Solve problems by using the equation $\phi = -\frac{GM}{r}$ for the potential in the field of a point mass.	
	$\phi = \frac{W}{m} = -\frac{GM}{r}$	
	Why gravitational potential values are always negative?	
	 As the gravitational force on the mass is attractive, the work done by an ext agent in bringing unit mass from infinity to any point in the field will be <u>negative</u> work{as the force exerted by the ext 	
	agent is <u>opposite</u> in direction to the displacement to ensure that $\Delta KE = 0$ }	
	- Hence by the definition of <i>negative work</i> , all values of ϕ are negative.	

	vork d → U	lone in bringing that mass <i>m</i> {№ = m φ = - GMm r	a mass <i>m</i> at a point in the gravita NOT: <i>unit mass,</i> or <i>a mass</i> } from in	finity to that point.

	2.	Definition of Field Strength	Force per unit positive charge $E = \frac{F}{q}$	Force per unit mass $g = \frac{F}{M}$		
	3.	Force between two <u>Point</u> Charges or Masses	Coulomb's Law: $F_{e} = \frac{Q_{1}Q_{2}}{4\pi\epsilon_{o}r^{2}}$ $E = \frac{Q}{4\pi\epsilon_{o}r^{2}}$	Newton's Law of Gravitation: $F_g = G \frac{GMm}{r^2}$		
	4.	Field Strength of isolated <u>Point</u> Charge or Mass	$E = \frac{Q}{4\pi\varepsilon_{o}r^2}$	$g = G \frac{GM}{r^2}$		
	5.	Definition of Potential	Work done in bringing a unit positive charge from infinity to the point.	Work done in bringing a unit mass from infinity to the point. $\phi = \frac{W}{M}$		
	6.	Potential of isolated Point Charge or Mass	$V = \frac{W}{Q}$ $V = \frac{Q}{4\pi\epsilon_{o}r}$	$\phi = -G \frac{M}{r}$		
	7.	Change in Potential Energy	$\Delta U = q \Delta V$	$\Delta U = m \Delta \phi$		
i. Analyse circular orbits in inverse square law fields by relating the grace centripetal acceleration it causes. Total Energy of a Satellite = GPE + KE = $(-\frac{GMm}{r}) + (\frac{1GMm}{2})$		ng the gravitational force to				
	Escape Speed of a Satellite					
E	By Conservation of Energy, Initial KE+ Initial GPE = Final KE + Final GPE $\frac{1}{2}mv_{E}^{2}$ + $(-\frac{GMm}{r})$ = 0 + 0					
E		Thus escape speed, $v_E = \sqrt{\frac{2GM}{R}}$				
E 11 12	-	escape speed, $v_E = \sqrt{\frac{2000}{R}}$				
E 11 1 2	- Thus e	escape speed, $v_E = \sqrt{\frac{26m}{R}}$ Escape speed of an object is i	ndependent of its mass			
E III 122 T N	- Thus e Note : For a s	Escape speed of an object is i satellite in circular orbit,	ndependent of its mass <u>the centripetal force is provided</u> roviding the centripetal force be			

	{This explains also why the Moon does not fall towards the Earth}	
j.	Show an understanding of geostationary orbits and their application.	
	Geostationary satellite is one which is <u>always above a certain point on the Earth</u> (as the Earth rotates about its axis.)	
	For a geostationary orbit: $T = 24$ hrs, orbital radius (& height) are fixed values from the centre of the Earth, ang velocity w is also a fixed value; rotates fr west to east. However, the <u>mass</u> of the satellite is <u>NOT a</u> <u>particular value</u> & hence the ke, gpe, & the centripetal force are also not fixed values {ie their values depend on the mass of the geostationary satellite.}	
	A geostationary orbit must lie in the <u>equatorial plane</u> of the earth because it <u>must</u> accelerate in a plane where the <i>centre</i> of Earth lies since the <u>net force</u> exerted on the satellite is the <u>Earth's gravitational force</u> , which is <u>directed towards the centre</u> of Earth.	
	{Alternatively, may explain by showing why it's impossible for a satellite in a non-equatorial plane to be geostationary.}	

Cha	pter 8: Oscillations

g.	Describe with graphical	l illustrations, the changes in displacement, velocity and acceleration during	
	simple harmonic motion	n.	

	svetem		
	system.		
	Damping	refers to the loss of energy from an oscillating system to the environment due to dissipative forces {eg, friction, viscous forces, eddy currents}	
	Light Damping:	The system <u>oscillates</u> about the equilibrium position with <u>decreasing amplitude</u> over a period of time.	
	Critical Damping:	The system does <u>not</u> oscillate & damping is just adequate such that the system returns to its equilibrium position in the <u>shortest</u> possible time.	
	Heavy Damping:	The damping is so great that the displaced object <u>never oscillates</u> but returns to its equilibrium position <u>very very slowly</u> .	
j.	Describe practical examples of forced oscillations and resonance.		
	Free Oscillation:	An oscillating system is said to be undergoing <i>free oscillations</i> if its oscillatory motion is <u>not</u> subjected to an external periodic driving force. The system oscillates at its natural freq.	
	Forced Oscillation:	In contrast to free oscillations, an oscillating system is said to undergo forced oscillations if it is subjected to an <u>input of energy from an external periodic</u> <u>driving force</u> The freq of the forced {or driven} oscillations will be <u>at the freq of the driving force</u> {called the driving frequency} ie. no longer at its own natural frequency.	
	Resonance:	A phenomenon whereby the <u>amplitude</u> of a system undergoing <u>forced</u> <u>oscillations</u> increases to a <u>maximum</u> . It occurs when <u>the frequency of the periodic driving force</u> is equal to the natural frequency of the system.	
	Effects of Damping on	Freq Response of a system undergoing forced oscillations	
	1) Resonant freg	uency decreases

k.	natural frequency of	now the amplitude of a forced oscillation changes with frequency near to the the system, and understand qualitatively the factors which determine the nd sharpness of the resonance.	
	Amplitude of forced	No damping Light damping Heavy damping f ₀	
I.		that there are some circumstances in which resonance is useful and other th resonance should be avoided.	

Examples of Useful Purposes of Resonance

- (a) Oscillation of a child's swing.
- (b) Tuning of musical instruments.
- (c) Tuning of radio receiver Natural frequency of the radio is adjusted so that it responds resonantly to a specific broadcast frequency.
- (d) Using microwave to cook food Microwave ovens produce microwaves of a frequency which is equal to the natural frequency of water molecules, thus causing the water molecules in the food to vibrate more violently. This generates heat to cook the food but the glass and paper containers do not heat up as much.
- (e) Magnetic Resonance Imaging (MRI) is used in hospitals to create images of the human organs.
- (f) Seismography the science of detecting small movements in the Earth's crust in order to locate centres of earthquakes.

Examples of Destructive Nature of Resonance

- (a) An example of a disaster that was caused by resonance occurred in the United States in 1940. The Tarcoma Narrows Bridge in Washington was suspended by huge cables across a valley. Shortly after its completion, it was observed to be unstable. On a windy day four months after its official opening, the bridge began vibrating at its resonant frequency. The vibrations were so great that the bridge collapsed.
- (b) High-pitched sound waves can shatter fragile objects, an example being the shattering of a wine glass when a soprano hits a high note.
- (c) Buildings that vibrate at natural frequencies close to the frequency of seismic waves face the possibility of collapse during earthquakes.

SECTION III THERMAL PHYSICS

Cha	Chapter 9: Thermal Physics		
	- Internal energy		
	 Temperature scales Specific heat capacity 		
	- Specific latent heat		
	- First law of thermodynamics		
	- The ideal gas equation		
	- Kinetic energy of a molecule		
a.	Show an understanding that internal energy is determined by the state of the system and that it can be expressed as the sum of a random distribution of kinetic and potential energies associated with the molecules of a system.		
	Internal Energy: is the sum of the kinetic energy of the molecules <u>due to its random motion</u> & the pe of the molecules due to the intermolecular forces.		
	<u>"Internal energy is determined by the state of the system". Explain what this means.</u> Internal energy is <u>determined by the values of the current state</u> and is <u>independent of how the state is</u>		
	arrived at. Thus if a system undergoes a series of changes from one state A to another state B, its change in internal energy is the same, regardless of which path {the changes in the p & V} it has taken to get from A to B.		
b.	Relate a rise in temperature of a body to an increase in its internal energy.		
	Since Kinetic Energy proportional to temp, and internal energy of the system = sum of its Kinetic Energy and Potential Energy, a rise in temperature will cause a rise in Kinetic Energy and thus an increase in internal energy.		
c.	Show an understanding that regions of equal temperature are in thermal equilibrium.		
	If two bodies are in thermal equilibrium , there is <u>no <i>net</i> flow of heat energy between them</u> and they have the <u>same temperature</u> . {NB: this <u>does not imply they must have the same <i>internal energy</i> as internal energy depends also on the <u>number of molecules</u> in the 2 bodies, which is <u>unknown</u> here}</u>		
d. e.	Show an understanding that there is an absolute scale of temperature which does not depend on the property of any particular substance, i.e. the thermodynamic scale. Apply the concept that, on the thermodynamic (Kelvin) scale, absolute zero is the temperature at which all substances have a minimum internal energy.		
	Thermodynamic (Kelvin) scale of temperature: theoretical scale that is <u>independent of the properties of</u> any particular substance.		
	An absolute scale of temp is a temp scale which does not depend on the property of any particular substance (ie the thermodynamic scale)		
	Absolute zero: Temperature at which <u>all</u> substances have a <u>minimum</u> internal energy {NOT: zero internal energy.}		
f.	Convert temperatures measured in Kelvin to degrees Celsius: T / K = T / $^{\circ}$ C + 273.15.		
	$T/K = T/^{0}C + 273.15$, by definition of the Celsius scale.		
g.	Define and use the concept of specific heat capacity, and identify the main principles of its determination by electrical methods.		
	Specific heat capacity is defined as the amount of heat energy needed to produce <u>unit temperature</u> <u>change</u> {NOT: by 1 K} for <u>unit mass {NOT: 1 kg}</u> of a substance, without causing a change in state. i.e. $c = \frac{Q}{m\Delta T}$		
	ELECTRICAL METHODS		
h.	Define and use the concept of specific latent heat, and identify the main principles of its determination by electrical methods.		

Specific latent heat of vaporisation is defined as the amount of heat energy needed to change unit mas substance from liquid phase to gaseous phase without a change of temperature. Specific latent heat of fusion is defined as the amount of heat energy needed to change unit mass substance from solid phase to liquid phase without a change of temperature i.e. $L = \frac{Q}{m}$ {for both cases of vaporisation & melting} The specific latent heat of vaporisation is greater than the specific latent heat of fusion for a given substance {N06P2Q2} During vaporisation, there is a greater increase in volume than in fusion; Thus more work is done against atmospheric pressure during vaporisation. The increase in vol also means the INCREASE IN THE (MOLECULAR) POTENTIAL ENERGY, & hence, internal energy, during vaporisation more than that during melting. Hence by 1st Law of Thermodynamics, heat supplied during vaporisation more than that during melting; hence $I_v > I_f$ {since Q = mI = $\Delta U - W$ } {Note: the use of comparative terms: greater, more, and > 1. 2. the increase in internal energy is due to an increase in the PE, NOT KE of molecules the system here is NOT to be considered as an ideal gas system (Similarly, you need to explain why, when a liq is boiling, thermal energy is being supplied, and yet, the temp of the liq does not change. (N97P3Q5, [4 m]) Explain using a simple kinetic model for matter why i., Melting and boiling take place without a change in temperature, The specific latent heat of vaporisation is higher than specific latent heat of fusion for the ii. same substance. iii. Cooling effect accompanies evaporation. Boiling Evaporation Melting Occurrence On the surface. Throughout the substance, at fixed temperature and pressure at all temperatures Spacing(vol) & Increase slightly Increase significantly **PE of molecules** Temperature & Remains constant during process Decrease for hence KE of remaining liquid molecules j. Recall and use the first law of thermodynamics expressed in terms of the change in internal energy, the heating of the system and the work done on the system. First Law of Thermodynamics: The increase in internal energy of a system is equal to the sum of the heat supplied to the system and the work done on the system. ie $\Delta U = W + Q$ where ΔU: Increase in internal energy of the system Q: Heat supplied to the system W: work done on the system {Need to recall the sign convention for all 3 terms} Work is done by a gas when it expands; work is done on a gas when it is compressed. W = area under pressure-volume graph. For constant pressure {isobaric process}, Work done = pressure $\times \Delta Volume$ **Isothermal process**: a process where $T = \text{const} \{\Rightarrow \Delta U = 0 \text{ for ideal gas} \}$

	ΔU for a cycle = 0 {since U \propto T, & ΔT = 0 for a cycle }		
k.	Recall and use the ideal gas equation pV = nRT where n is the amount of gas in moles.		
	 Equation of state for an ideal gas: p V = n R T, where T is in Kelvin {NOT: ⁰C}, n: no. of moles. p V = N k T, where N: no. of molecules, k:Boltzmann const Ideal Gas: a gas which obeys the ideal gas equation pV = nRT FOR ALL VALUES OF P, V & T 		
Ι.	Show an understanding of the significance of the Avogadro constant as the number of atoms in 0.012 kg of carbon-12.		
	Avogadro constant: defined as the number of atoms in 12 g of carbon-12. It is thus the number of particles (atoms or molecules) in one mole of substance.		
m .	Use molar quantities where one mole of any substance is the amount containing a number of		
	particles equal to the Avogadro constant.		
	· · ·		
	?		
n.	Recall and apply the relationship that the mean kinetic energy of a molecule of an ideal gas is		
•••	proportional to the thermodynamic temperature to new situations or to solve related problems.		
	For an <u>ideal</u> gas, internal energy U = Sum of the KE of the molecules <u>only</u> {since PE = 0 for ideal gas}		
	ie $U = N x^{1/2} m \langle c^2 \rangle = N x \frac{3}{2} kT$ {for monatomic gas}		
	- U depends on T and number of molecules N.		
	- $\mathbf{U} \propto \mathbf{T}$ for a <u>given number of molecules</u>		
	Ave KE of a molecule, $\frac{1}{2}$ m <c<sup>2> \propto T { T in K: not $^{\circ}$C }</c<sup>		

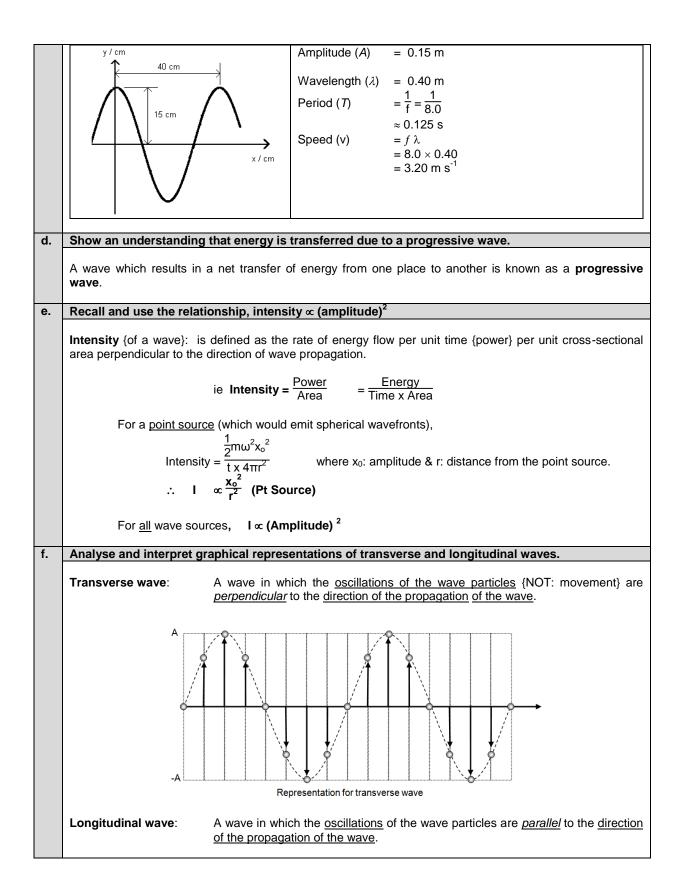

SECTION IV WAVES

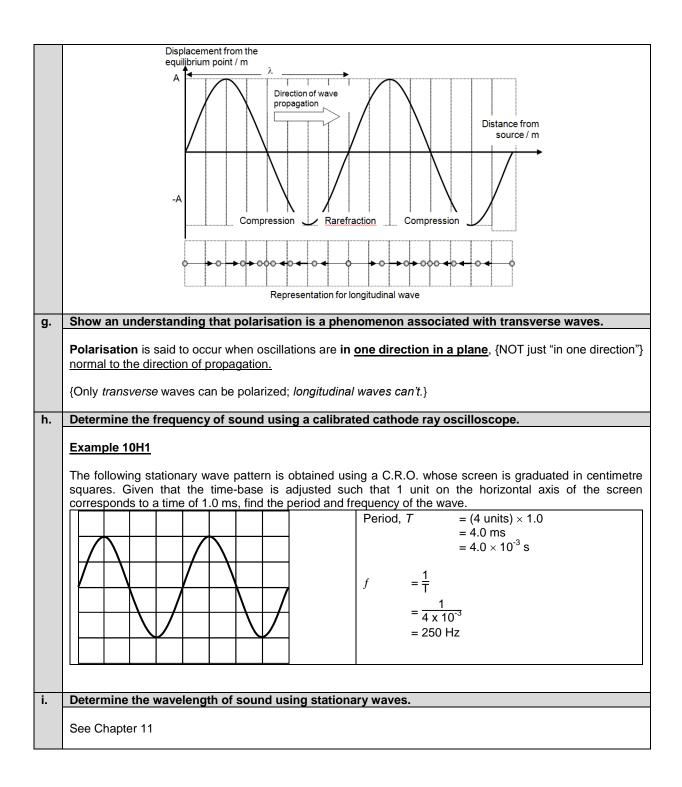

Cha	hapter 10: Wave Motion				
	 Progressive Waves Transverse and Longitudinal Waves 				
	- Polarisation				
 Determination of frequency and wavelength a. Show an understanding and use the terms displacement, amplitude, phase different 					
	freque	ency, wavelength and spe	eed.		
	(a)	Displacement (y):	Position of an oscillating particle from its equilibrium position.		
	(b)	Amplitude (y ₀ or A):	The maximum magnitude of the displacement of an oscillating particle from its equilibrium position.		
	(c)	Period (T):	Time taken for a particle to undergo one complete cycle of oscillation.		
	(d)	Frequency (f):	Number of oscillations performed by a particle per unit time.		
	(e)	Wavelength (λ):	For a progressive wave, it is the distance between any two <u>successive</u> particles that are <u>in phase</u> , e.g. it is the distance between 2 consecutive crests or 2 troughs.		
	(f)	Wave speed (v):	The speed at which the waveform travels in the direction of the propagation of the wave.		
	(g)	Wave front:	A line or surface joining points which are at the same state of oscillation, i.e. in phase, e.g. a line joining crest to crest in a wave.		
	(h)	Ray:	The path taken by the wave. This is used to indicate the direction of wave propagation. Rays are always at right angles to the wave fronts (i.e. wave fronts are always perpendicular to the direction of propagation).		
b.	Deduc	ce, from the definitions of	f speed, frequency and wavelength, the equation $v = f\lambda$		
	From the definition of speed, Speed = $\frac{\text{Distance}}{\text{Time}}$		Speed = $\frac{\text{Distance}}{\text{Time}}$		
	A wav	e travels a distance of one	wavelength, λ , in a time interval of one period, <i>T</i> .		
		equency, f, of a wave is equ			
			fore, speed, $v = \frac{\lambda}{T}$		
			$=(\frac{1}{T})\lambda$		
	Hence	e, v = fλ	$= f\lambda$		
6	Pocal	Land use the equation y	- f)		
C.	Recal	I and use the equation v =	= 1,,		
	Example 10C1 A wave travelling in the positive <i>x</i> direction is showed in the figure. Find the amplitude, wavelength, period and speed of the wave if it has a frequency of 8.0 Hz.				

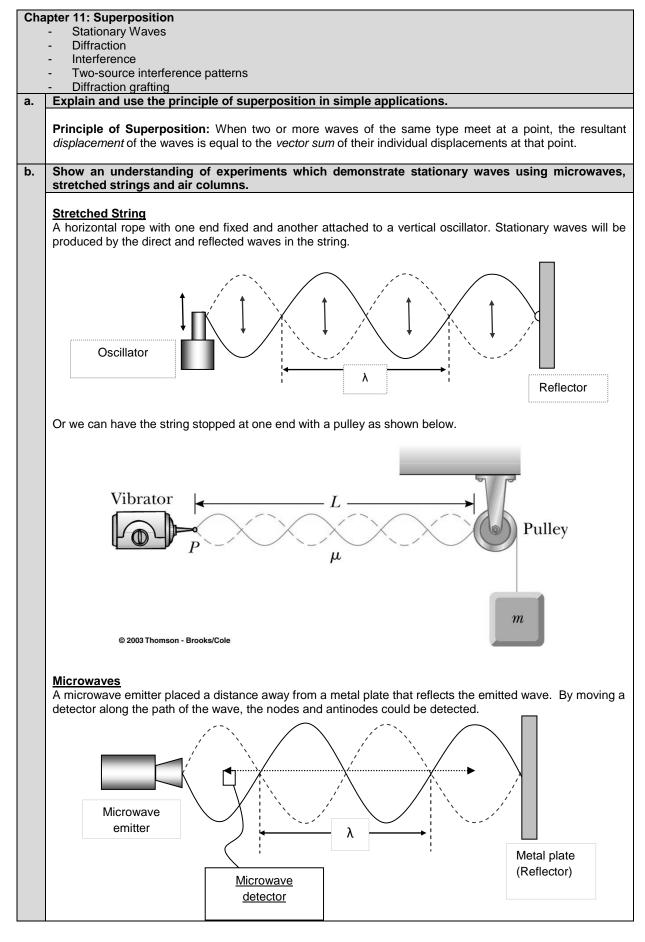

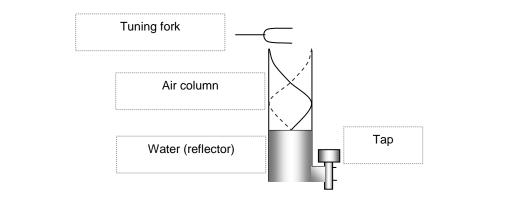

<u>Air column</u>

A tuning fork held at the mouth of a open tube projects a sound wave into the column of air in the tube. The length of the tube can be changed by varying the water level. At certain lengths of the tube, the air column resonates with the tuning fork. This is due to the formation of stationary waves by the <u>incident</u> and <u>reflected</u> sound waves at the water surface.

c. Explain the formation of a stationary wave using a graphical method, and identify nodes and antinodes.

Stationary (Standing) Wave) is one

- whose waveform/wave profile does not advance {move},
- where there is no net transport of energy, and
- where the positions of antinodes and nodes do not change (with time).

A stationary wave is formed when two <u>progressive</u> waves of the same <u>frequency</u>, <u>amplitude</u> and <u>speed</u>, travelling in <u>opposite directions</u> are superposed. {Assume boundary conditions are met}

	Stationary Waves	Progressive Waves
Amplitude	Varies from maximum at the anti-nodes to	Same for all particles in the wave
	zero at the nodes.	(provided no energy is lost).
Wavelength	Twice the distance between a pair of	The distance between two consecutive
	adjacent nodes or anti-nodes.	points on a wave, that are in phase.
Phase	Particles in the same segment/ between 2	All particles within one wavelength have
	adjacent nodes, are in phase. Particles in	different phases.
	adjacent segments are in anti-phase.	
Wave Profile	The wave profile does not advance.	The wave profile advances.
Energy	No energy is transported by the wave.	Energy is transported in the direction of
		the wave.

Node is a region of destructive superposition where the waves <u>always</u> meet <u>out of phase by π radians</u>. Hence displacement here is <u>permanently zero</u> {or minimum}.

Antinode is a region of constructive superposition where the waves <u>always</u> meet <u>in phase</u>. Hence a particle here <u>vibrates</u> with <u>maximum amplitude</u> {but it is NOT a pt with a *permanent* large displacement!}

Dist between 2 successive nodes/antinodes = $\frac{\Lambda}{2}$

<u>Max pressure change</u> occurs at the <u>nodes</u> {NOT the antinodes} because every node changes fr being a pt of compression to become a pt of rarefaction {half a period later}

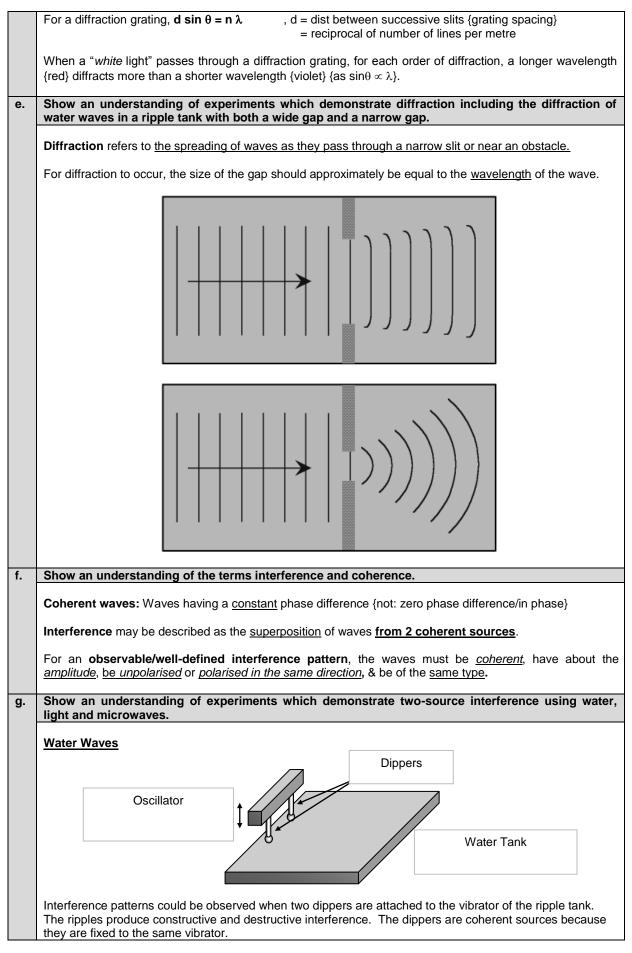

d. Explain the meaning of the term diffraction.

j. Recall and solve problems by using the formula $dsin\theta = n\lambda$ and describe the use of a diffraction grating to determine the wavelength of light. (The structure and use of the spectrometer is not required.)

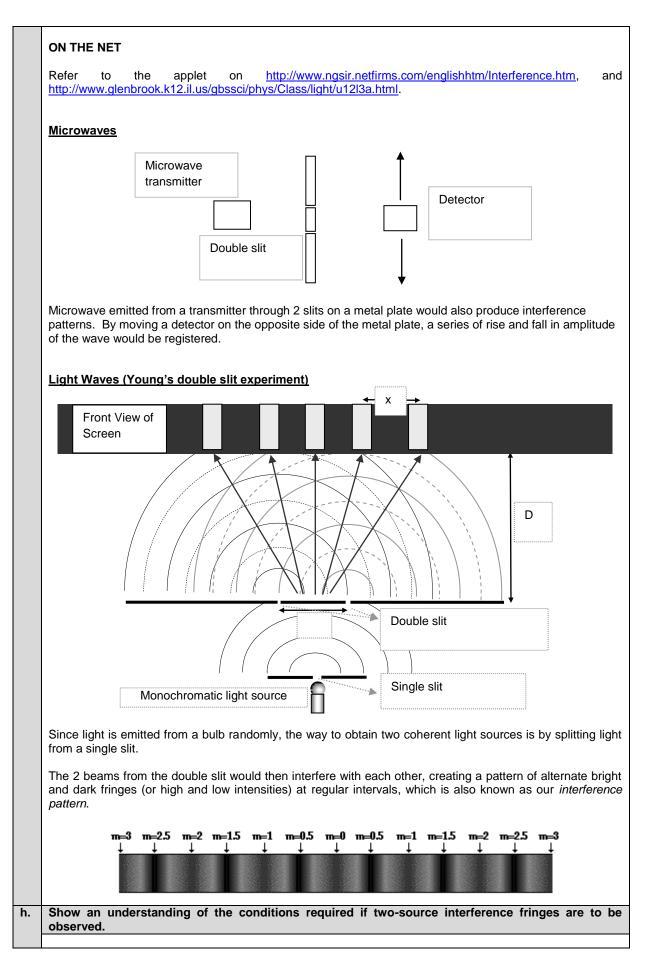

Diffraction: refers to the <u>spreading</u> {or bending} of waves when they pass through an <u>opening {gap}</u>, or <u>round an obstacle</u> (into the "shadow" region). {Illustrate with diag}

For significant diffraction to occur, the size of the gap $\approx \lambda$ of the wave

	Condition for Constructive Interference at a pt P:
	phase difference of the 2 waves at P = 0 {or 2π , 4π , etc}
	Thus, with 2 <i>in-phase</i> sources, * implies path difference = $n\lambda$; with 2 <i>antiphase</i> sources: path difference = $(n + \frac{1}{2})\lambda$
	Condition for Destructive Interference at a pt P:
	phase difference of the 2 waves at P = π { or 3π , 5π , etc }
	With 2 <i>in-phase</i> sources, + implies path difference = (n+ $\frac{1}{2} \lambda$), with 2 <i>antiphase</i> sources: path difference = n λ
i.	Recall and solve problems using the equation $\lambda = \frac{\lambda D}{a}$ for double-slit interference using light.
	a a lot double-sit interference dsing light.
	Fringe separation $\mathbf{x} = \frac{\lambda \mathbf{D}}{\mathbf{a}}$, if a< <d <i="" double="" interference="" of="" only="" slit="" to="" young's="" {applies="">light, le, NOT for microwaves, sound waves, water waves}</d>
	Fringe separation $\mathbf{x} = \frac{\lambda \mathbf{D}}{\mathbf{a}}$, if a << D {applies only to Young's Double Slit interference of <i>light</i> ,

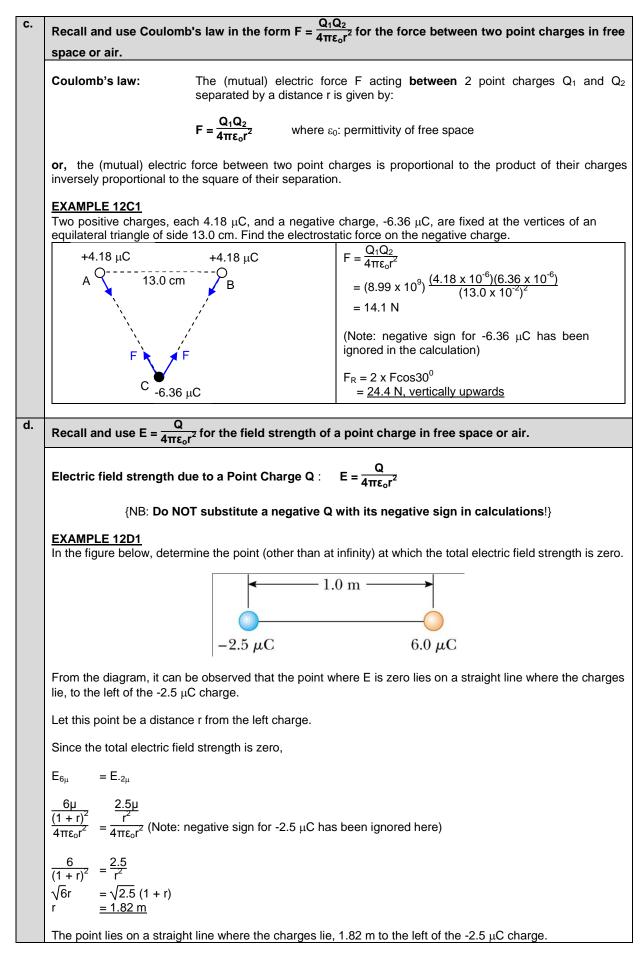

SECTION V ELECTRICITY & MAGNETISM

	Relation between E and V: $E = -\frac{dV}{dr}$ i.e. The electric field strength at a pt is numerically equal to the potential gradient at that pt. NB: Electric field lines point in direction of <u>decreasing</u> potential {ie from high to low pot}.
j.	Use the equation V = $\frac{Q}{4\pi\epsilon_o r}$ for the potential in the field of a point charge.
	Electric potential energy U of a charge Q at a pt where the potential is V: $U = QV$ \rightarrow Work done W on a charge Q in moving it across a pd ΔV : $W = Q \Delta V$
	Electric Potential due to a <i>point</i> charge Q : $V = \frac{Q}{4\pi\epsilon_0 r}$ {in List of Formulae}
	{NB: Substitute Q with its sign}
k.	Recognise the analogy between certain qualitative and quantitative aspects of electric field and gravitational fields.
	See 7h

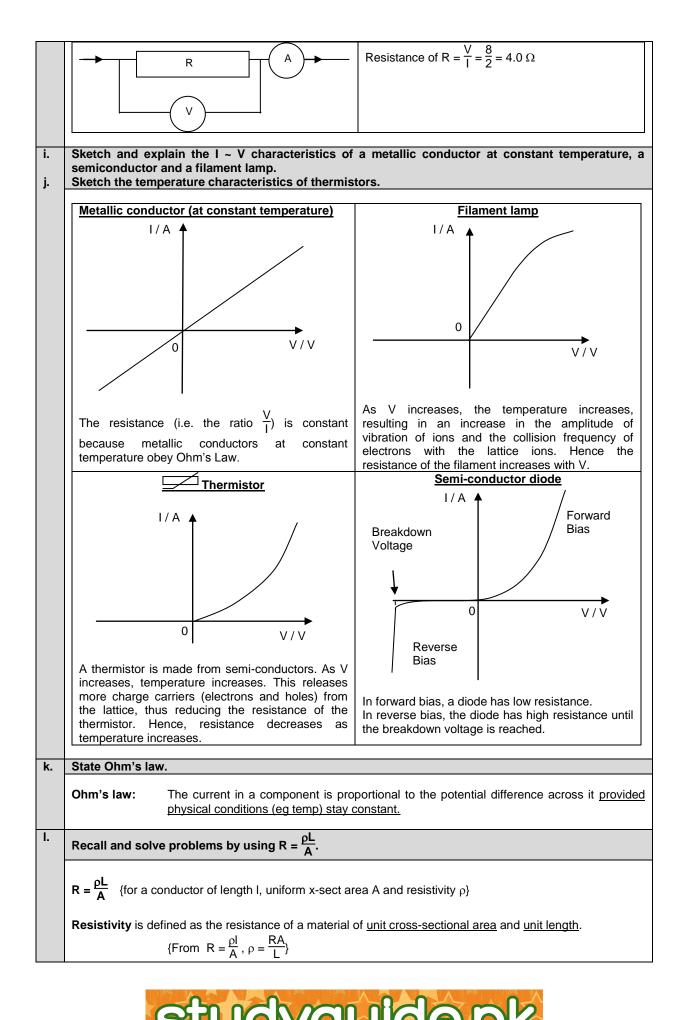

Cha	pter 13: Current of Electricity
	- Electric current
	 Potential difference Resistance and Resistivity
	- Sources of electromotive force
a.	Show an understanding that electric current is the rate of flow of charged particles.
	Electric current is the rate of flow of <i>charge</i> . {NOT: charged particles}
b.	Define charge and coulomb.
	Electric charge Q passing a point is defined as the product of the (steady) current at that point and the time for which the current flows, ie Q = I t
	One coulomb is defined as the charge flowing per <u>second</u> pass a point at which the current is <u>one ampere.</u>
с.	Recall and solve problems using the equation Q = It.
	EXAMPLE 13C1 An ion beam of singly-charged Na ⁺ and K ⁺ ions is passing through vacuum. If the beam current is 20μ A, calculate the total number of ions passing any fixed point in the beam per second. (The charge on each ion is 1.6×10^{-19} C.)
	Current, $I = \frac{Q}{t} = \frac{Ne}{t}$ where N is the no. of ions and e is the charge on one ion.
	No. of ions per second $=\frac{N}{t}$
	$= \frac{l}{e}$ = $\frac{20 \times 10^{-6}}{1.6 \times 10^{-79}}$ = 1.25 × 10 ⁻¹⁴
d.	Define potential difference and the volt.
	Potential difference is defined as the energy transferred from electrical energy to other forms of energy W
	when <u>unit</u> charge passes through an electrical device, ie $V = \frac{W}{Q}$
	P. D. = Energy Transferred / Charge = Power / Current or, is the ratio of the power supplied to the device to the current flowing, ie $V = \frac{P}{I}$
	The volt: is defined as the potential difference between 2 pts in a circuit in which <u>one joule of energy is</u> <u>converted</u> from electrical to non-electrical energy when <u>one coulomb</u> passes from 1 pt to the other, ie 1 volt
	= One joule per coulomb
	Difference between Potential and Potential Difference (PD): The potential at a point of the circuit is due to the amount of charge present along with the energy of the charges. Thus, the potential along circuit drops from the positive terminal to negative terminal, and potential differs from points to points.
	Potential Difference refers to the difference in potential between any given two points. For example, if the potential of point A is 1 V and the potential at point B is 5 V, the PD across AB , or V_{AB} , is 4 V. In addition, when there is no energy loss between two points of the circuit, the potential of these points is same and thus the PD across is 0 V.
е.	Recall and solve problems by using V = $\frac{W}{Q}$
	EXAMPLE 13E1 A current of 5 mA passes through a bulb for 1 minute. The potential difference across the bulb is 4 V.

	Calculate			
	Galculate			
	(a) The amount of charge passing through the bulb in 1 minute.			
	Charge Q = I t = $5 \times 10^{-3} \times 60$			
	$= 5 \times 10 \times 60$ $= 0.3 \text{ C}$			
	(b) The work done to operate the bulb for 1 minute.			
	Potential difference across the bulb = $\frac{W}{\Omega}$			
	$4 \qquad = \frac{W}{0.3}$			
	Work done to operate the bulb for 1 minute $= 0.3 \times 4$			
	= 1.2 J			
f.	Recall and solve problems by using $P = VI$, $P = I^2R$.			
	\mathcal{M}^2			
	Electrical Power, P = V I = $I^2 R$ = $\frac{V^2}{R}$			
	{Brightness of a lamp is determined by the power dissipated, NOT: by V, or I or R alone}			
	EXAMPLE 13F1			
	A high-voltage transmission line with a resistance of 0.4 Ω km ⁻¹ carries a current of 500 A. The line is at a			
	potential of 1200 kV at the power station and carries the current to a city located 160 km from the power station. Calculate			
	(a) the power loss in the line.			
	The power loss in the line P = $I^2 R_1$			
	$= 500^2 \times 0.4 \times 160$			
	= 16 MW			
	(b) the fraction of the transmitted power that is lost.			
	The total power transmitted $= IV$			
	The total power transmitted $= 1 V$ = 500 × 1200 × 10 ³			
	= 600 MW			
	16			
	The fraction of power loss $=\frac{16}{600}$			
	= 0.267			
g.	Define resistance and the ohm.			
9.				
	Resistance is defined as the ratio of the potential difference across a component to the current flowing			
	through it, ie $\mathbf{R} = \frac{\mathbf{v}}{\mathbf{I}}$			
	{It is NOT <u>defined</u> as the gradient of a V-I graph; however for an <u>ohmic</u> conductor, its resistance <u>equals</u> the			
	gradient of its V-I graph as this graph is a straight line which passes through the origin}			
	The Ohm: is the resistance of a resistor if there is a current of 1 A flowing through it when the pd across it			
	is 1 V, ie, 1 Ω = One volt per ampere			
h.	Recall and solve problems by using V = IR.			
	EXAMPLE 13H1 In the circuit below, the voltmeter reading is 8.00 V and the ammeter reading is 2.00 A. Calculate the			
	resistance of R.			

EXAMPLE 13L1

Calculate the resistance of a nichrome wire of length 500 mm and diameter 1.0 mm, given that the resistivity of nichrome is $1.1 \times 10^{-6} \Omega$ m.

Resistance, R

$$=\frac{(1.1 \times 10^{-6})(500 \times 10^{-3})}{\pi \left(\frac{1 \times 10^{-3}}{2}\right)^2}$$

= 0.70 Ω

 $= \frac{\rho}{\Delta}$

m. Define EMF in terms of the energy transferred by a source in driving unit charge round a complete circuit.

Electromotive force Emf is defined as the energy transferred/converted from <u>non-electrical forms of energy</u> into electrical energy when <u>unit</u> charge is moved round a complete circuit.

EMF = Energy Transferred per unit charge,
ie E =
$$\frac{W}{O}$$

n. Distinguish between EMF and P.D. in terms of energy considerations.

EMF refers to the electrical energy generated from non-electrical energy forms, whereas PD refers to electrical energy being changed into non-electrical energy.

For example,

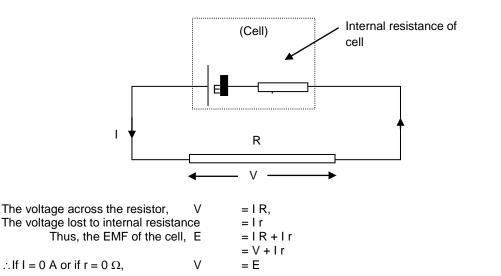

ie

EMF Sources	Energy Change	PD across	Energy Change
Chemical Cell	Chem -> Elec	Bulb	Elec -> Light
Generator	Mech -> Elec	Fan	Elec -> Mech
Thermocouple	Thermal -> Elec	Door Bell	Elec -> Sound
Solar Cell	Solar -> Elec	Heating element	Elec -> Thermal

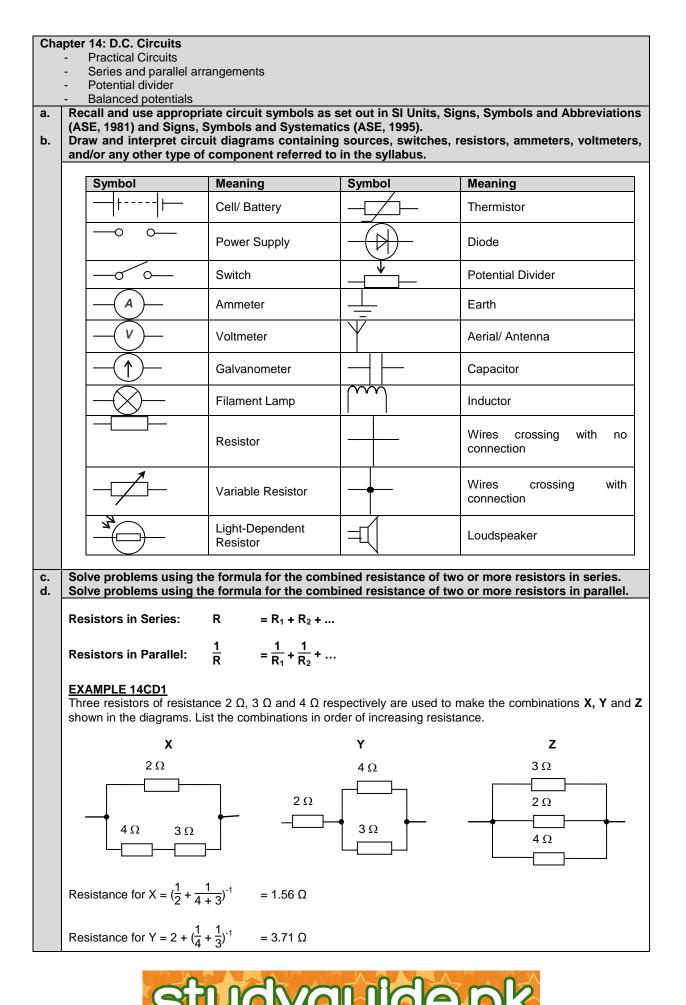

o. Show an understanding of the effects of the internal resistance of a source of EMF on the terminal potential difference and output power.

Internal resistance is the resistance to current flow within the power source. It reduces the *potential difference* (not EMF) across the terminal of the power supply *when it is delivering a current*.

Consider the circuit below:

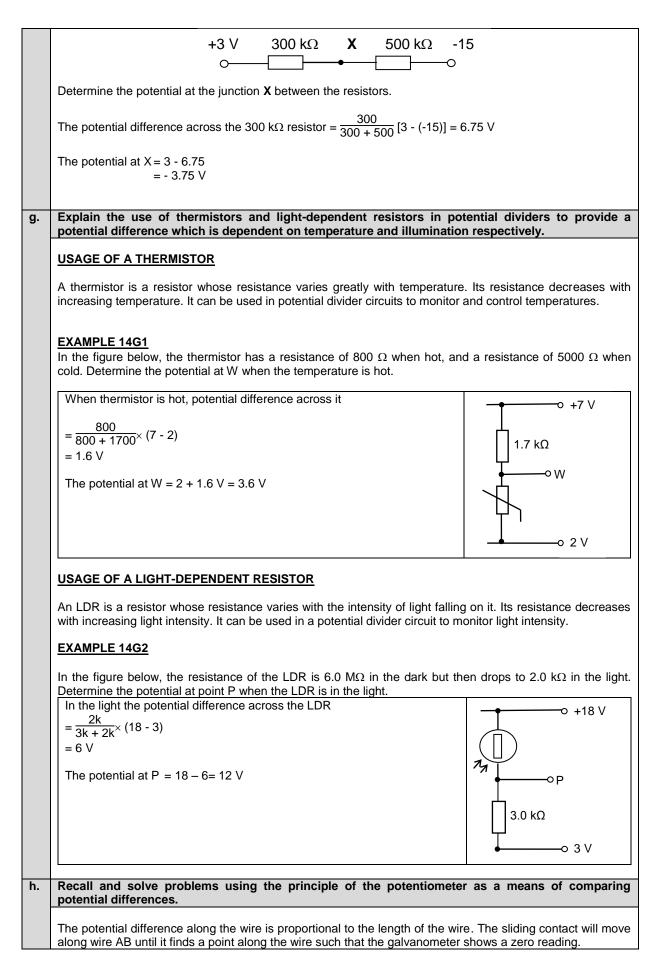

Resistance for Z = $(\frac{1}{3} + \frac{1}{2} + \frac{1}{4})^{-1}$ = 0.923 Ω Therefore, the combination of resistors in order of increasing resistance is Z X Y. Solve problems involving series and parallel circuits for one source of e.m.f. e. EXAMPLE 14E1 **E.g. 4** Referring to the circuit drawn, determine the value of I₁, I and R, the combined resistance in the circuit $E = I_1 (160) = I_2 (4000) = I_3 (32000)$ 2 V $= \frac{2}{160} = 0.0125 \text{ A}$ $= \frac{2}{4000} = 5 \times 10^{-4} \text{ A}$ I_1 **160** Ω 1 I_2 $=\frac{2}{32000}$ = 6.25 × 10⁻⁵ A Т I₃ 4000 Ω 12 Since $I = I_1 + I_2 + I_3$, I = 13.1 mAApplying Ohm's Law, $R = \frac{2}{13.1 \times 10^{-3}}$ 32000 Ω I_3 = 153 Ω EXAMPLE 14E2 A battery with an EMF of 20 V and an internal resistance of 2.0 Ω is connected to resistors R₁ and R₂ as shown in the diagram. A total current of 4.0 A is supplied by the battery and R₂ has a resistance of 12 Ω. Calculate the resistance of R_1 and the power supplied to each circuit component. $E - I r = I_2 R_2$ 2Ω $20 - 4(2) = I_2(12)$ $I_2 = 1A$ 20 V Therefore, $I_1 = 4 - 1 = 3 A$ 4 A R₁ $E - Ir = I_1 R_1$ 12 = 3 R₁ Therefore. R1 = 4 R_2 = $(I_1)^2 R_1$ = 36 W Power supplied to R₁ Power supplied to R₂ $(I_2)^2 R_2$ = 12 W Show an understanding of the use of a potential divider circuit as a source of variable p.d. f. For potential divider with 2 resistors in series, Potential drop across R₁, $V_1 = \frac{R_1}{R_1 + R_2} X PD$ across R₁ & R₂ Potential drop across R₂, $V_1 = \frac{R_2}{R_1 + R_2} X PD$ across R₁ & R₂ EXAMPLE 14F1 Two resistors, of resistance 300 k Ω and 500 k Ω respectively, form a potential divider with outer junctions maintained at potentials of +3 V and -15 V.

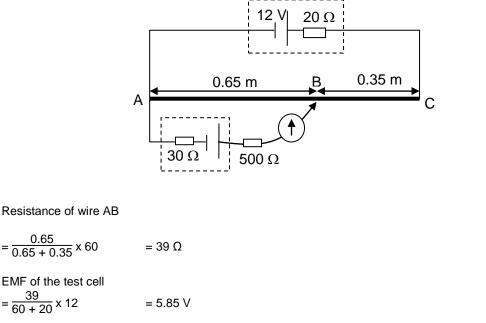

When the galvanometer shows a zero reading, the current through the galvanometer (and the device that is being tested) is zero and the potentiometer is said to be "balanced".

If the cell has negligible internal resistance, and if the potentiometer is balanced,

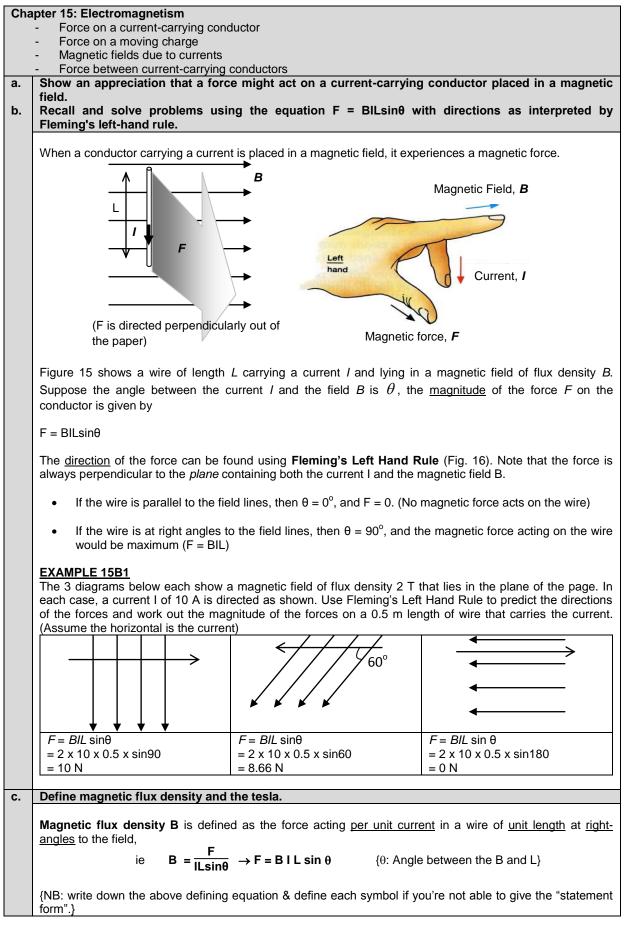

EMF / PD of the unknown source, V = $\frac{L_1}{L_1 + L_2} \times E$

EXAMPLE 14H1

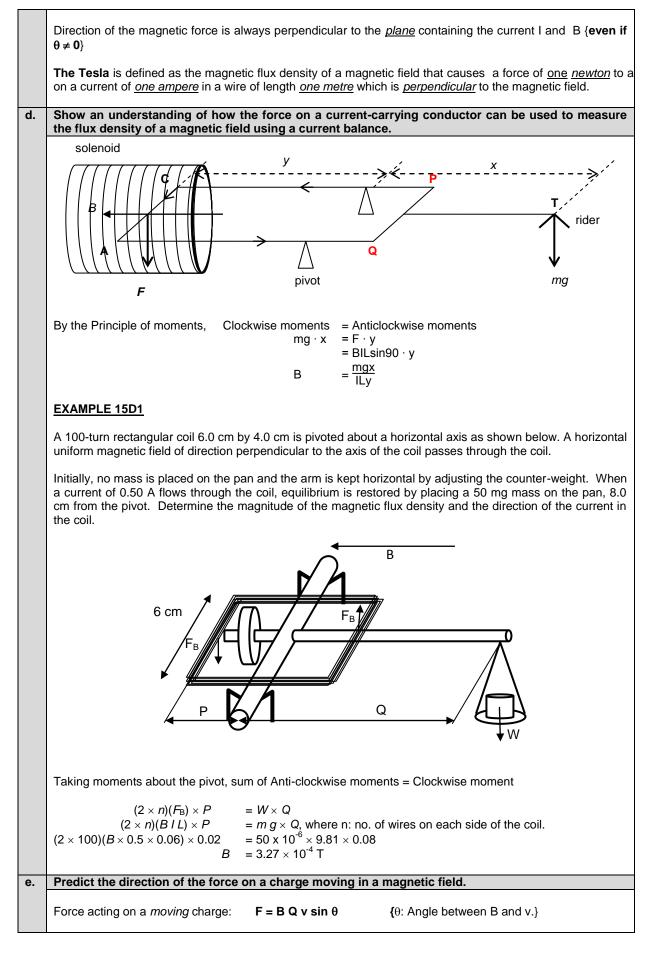

In the circuit shown, the potentiometer wire has a resistance of 60 Ω . Determine the EMF of the unknown cell if the balanced point is at B.

	The <u>direction</u> of this force may be found by using Fleming's left hand rule. The angle θ determines the type of path the charged particle will take when moving through a uniform magnetic field:
	• If $\theta = 0^\circ$, the charged particle takes a straight path since it is not deflected ($F = 0$)
	 If θ = 90°, the charged particle takes a circular path since the force at every point in the path is perpendicular to the motion of the charged particle.
	Since F is <u>always</u> be <u>perpendicular</u> to v {even if $\theta \neq 0$ },
	the magnetic force can provide the centripetal force, \rightarrow Bqv $=\frac{mv^2}{r}$
f.	Recall and solve problems using F = BQv sinθ.
	EXAMPLE 15F1
	An electron moves in a circular path in vacuum under the influence of a magnetic field.
	x x x e x x
	x x x x x x x x x x x x x x x x x x x
	x x x x x
	X X X X X
	The radius of the path is 0.010 m and the flux density is 0.010 T. Given that the mass of the electron is 9.11 x 10^{-31} kg and the charge on the electron is -1.6×10^{-19} C, determine
	(i) whether the motion is clockwise or anticlockwise; The magnetic force on the electron points towards the centre of the circular path; hence using Fleming's left hand rule, we deduce that the current I points to the left. The electron must be moving clockwise.
	(ii) the velocity of the electron. Bqv $= \frac{mv^2}{r}$
	$v = \frac{Bqr}{m}$
	$= \frac{(0.010)(1.6 \times 10^{-19})(0.010)}{9.11 \times 10^{-31}}$
	$= \frac{9.11 \times 10^{-31}}{9.11 \times 10^{-31}}$ = 1.76 x 10 ⁷ m s ⁻¹
g.	Describe and analyse deflections of beams of charged particles by uniform electric and uniform magnetic fields.
	Use Fleming's Left Hand Rule to analyse, then apply Parabolic Motion to analyse.
h.	Explain how electric and magnetic fields can be used in velocity selection for charged particles.
	Crossed-Fields in Velocity Selector:
	A setup whereby an E-field and a B-field are <u>perpendicular</u> to each other such that they exert <u>equal & opposite forces</u> on a moving charge {if the velocity is "a certain value"}
	I.e., if Magnetic Force = Electric Force B q $v = q E$
	V = E
	Only particles with speed = $\frac{E}{B}$ emerge from the cross-fields <u>undeflected</u> .
	For particles with speed > $\frac{E}{B}$, Magnetic Force > Electric Force
	For particles with speed $< \frac{E}{B}$, Magnetic Force $<$ Electric Force
i.	Sketch flux patterns due to a long straight wire, a flat circular coil and a long solenoid.

EXAMPLE 15K1

A long length of aluminium foil ABC is hung over a wooden rod as shown below. A large current is momentarily passed through the foil in the direction ABC, and the foil moves.

(i) Draw arrows to indicate the directions in which AB and BC move

Since currents in AB and BC are 'unlike' currents (they are flowing in opposite directions), the two foil sections AB and BC will repel each other.

(ii) Explain why the foil moves in this way

The current in the left foil AB produces a magnetic field in the other (BC). According to the Right Hand Grip Rule & Fleming's Left Hand Rule, the force on BC is away from and perpendicular to AB. By a similar consideration, the force on AB is also away from BC. Thus the forces between the foils are repulsive.

Cha		6: Electromagnetic Induction lagnetic flux			
		aws of electromagnetic induction ne magnetic flux and the weber.			
a.	Deni	e magnetic flux and the weber.			
		romagnetic induction refers to the phenomenon where an emf is induced when the magnetic flux linking a uctor changes.			
		Magnetic Flux is defined as the product of the magnetic flux density and the area <u>normal</u> to the field through which the field is passing. It is a scalar quantity and its S.I. unit is the weber (Wb).			
		$\phi = B A$			
		Weber is defined as the magnetic flux if a flux density of <u>one</u> tesla passes <u>perpendicularly</u> through an of <u>one square metre</u> .			
b.	Reca	II and solve problems using ϕ = BA.			
	A ma	MPLE 16B1 gnetic field of flux density 20 T passes down through a coil of of wire, making an angle of 60° to the plane coil as shown. The coil has 500 turns and an area of 25 cm ² . Determine:			
	(i)	the magnetic flux through the coil			
		60°			
	φ	= B A = 20 (sin 60°) 25×10^{-4}			
		$= 20 (\sin 100) 23 \times 10$ = 0.0433 Wb			
	<u>(ii)</u>	the flux linkage through the coil			
	Φ	= N (b)			
	Ŧ	$= 500 \times 0.0433 = 21.65 \text{ Wb}$			
C.	Dofir	ne magnetic flux linkage.			
0.	Dem	e magnetie nux minage.			
	Magi the c	netic Flux Linkage is the product of the magnetic flux passing through a coil and the number of turns of bil.			
		$\Phi = N \phi = N B A$			
d.	-	from appropriate experiments on electromagnetic induction:			
	i.	That a changing magnetic flux can induce an e.m.f. in a circuit,			
		E R			
		In the set up shown above, when the switch S connected to coil A is closed, the galvanometer needle connected to coil B moves to 1 side momentarily.			
		And when the switch S is opened, the galvanometer needle moves to the other side momentarily.			
		At the instant when switch S is either opened or closed, there is a change in magnetic flux in coil A.			
		The movement in the needle of the galvanometer indicates that when there is a change in magnetic flux in coil A, a current passes through coil B momentarily. This suggests that an EMF is generated in			

		coil B momentarily.				
	ii.	That the direction of the induced e.m.f. opposes the change producing it,				
		See below				
	iii.	The factors affecting the magnitude of the induced e.m.f.				
		When a magnet is pushed into a coil as shown, the galvanometer deflects in one direction momentarily.				
		When the magnet is not moving, the galvanometer shows no reading.				
		When the magnet is withdrawn from the coil, the galvanometer deflects in the opposite direction momentarily.				
		When the magnet is moved, its field lines are being "cut" by the coil. This generates an induced EMF in the coil that produces an induced current that flows in the coil, causing the deflection in the ammeter.				
		The magnitude of the deflection depends on the magnetic field density B, the speed of motion v of the magnet, and the number of turns N in the coil.				
e.	Reca	II and solve problems using Faraday's law of electromagnetic induction and Lenz's law.				
	Faraday's Law The magnitude of <i>induced</i> EMF is directly proportional/equal to the rate of <u>change</u> of <i>magnetic flux-linkag</i>					
		$ \mathbf{E} = \frac{\mathrm{d}NBA}{\mathrm{d}t}$				
	The o	's Law direction of the induced EMF is such that <u>its effects</u> oppose the <u>change which causes it</u> , or The induced nt in a closed loop must flow in such a direction that its effects opposes the flux change {or change} produces it				
	Expla	MPLE 16E1 ain how Lenz's Law is an example of the law of conservation of energy: trate with diagram of a coil "in a complete circuit", bar magnet held in hand of a person {= external t)}				
	-	As the ext agent causes the magnet to approach the coil, by Lenz's law, a current is induced in such a direction that the coil repels the approaching magnet.				
	-	Consequently, work has to be done by the external agent to overcome this opposition, and				
	-	It is this work done which is the source of the electrical energy {Not: induced emf}				
	For a	straight conductor "cutting across" a B-field: E = B L vsinθ				
	For a	coil rotating in a B-field with angular frequency ω :				

1	ο cos ω t, ο sin ω t,	if φ = BAsinωt if φ = BAcosωt		
{Whether ϕ = BAsin ω t	, or = BAcosω	would depend on the initi	al condition}	
The induced EMF is t	he <u>negative of</u>	the gradient of the $\phi \sim t$	graph {since E = $-\frac{dN\phi}{dt}$ }	
ightarrow the graphs of E vs t	t& o∣vst,fo	the <u>rotating coil</u> have a <u>pl</u>	nase difference of 90 ⁰ .	
Explain simple appl	ications of el	ctromagnetic inductior

studyguide.pk

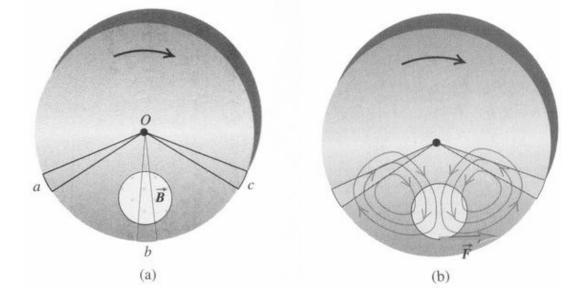

magnetic field through the secondary coil is no longer zero and changes with time, since the current is ac. The changing magnetic flux causes an induced voltage to appear in the secondary coil, which triggers the circuit breaker to stop the current. ELCB works very fast (in less than a millisecond) and turn off the current before it reaches a dangerous level.

5 Eddy current brake

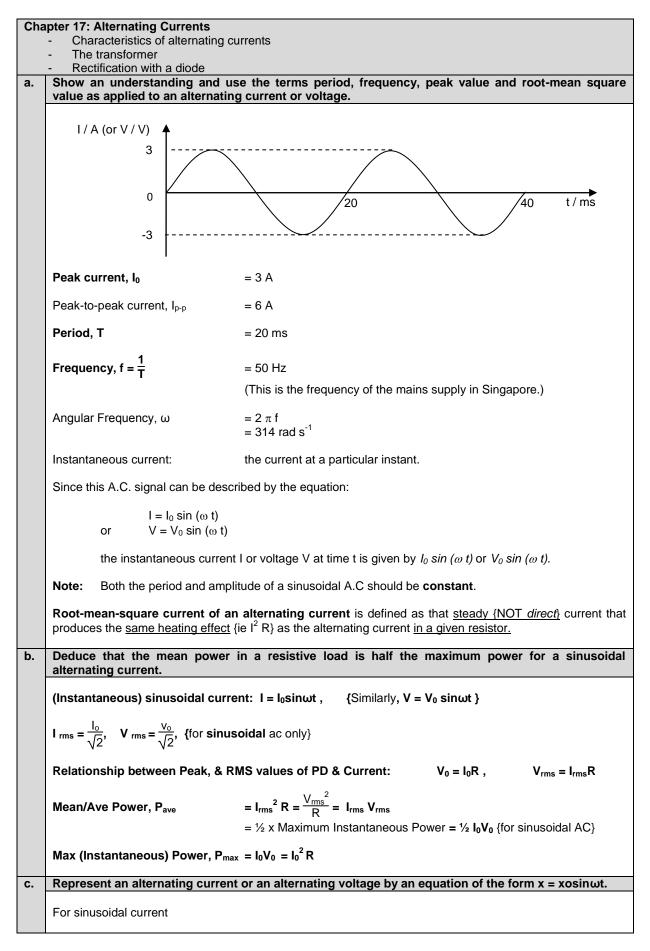

An **eddy current brake**, like a conventional friction brake, is responsible for slowing an object, such as a train or a roller coaster. Unlike friction brakes, which apply pressure on two separate objects, eddy current brakes slow an object by creating eddy currents through electromagnetic induction which create resistance, and in turn either heat or electricity.

Consider a metal disk rotating clockwise through a perpendicular magnetic field but confined to a limited portion of the disk area. (Compare this with the Faraday's disk earlier)

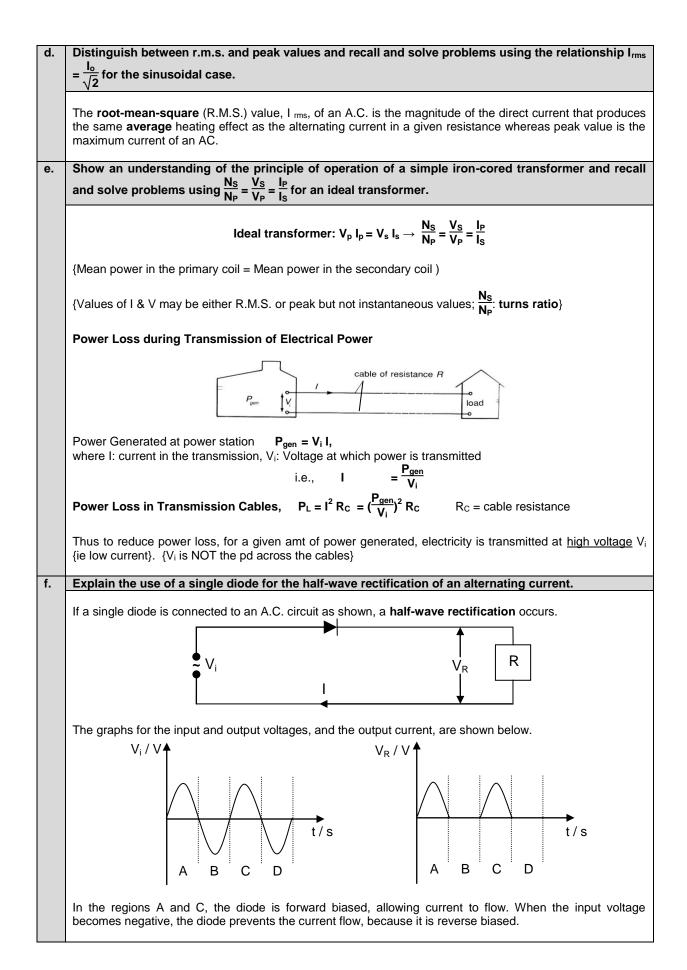

Sector Oa and Oc are not in the field, but they provide return conducting path, for charges displaced along Ob to return from b to O. The result is a circulation of eddy current in the disk. The current experiences a magnetic force that opposes the rotation of the disk, so this force must be to the right. The return currents lie outside the field, so they do not experience magnetic forces. The interaction between the eddy currents and the field causes a braking action on the disk.

а.		n appreciation of the particulate nature of electromagnetic radiation.
	A photo	on is a discrete packet {or quantum} of energy of an electromagnetic radiation/wave.
b.	Recall	and use E = hf
	Energy	of a photon, $\mathbf{E} = \mathbf{h} \mathbf{f} = \frac{\mathbf{hc}}{\lambda}$ where h: Planck's constant
	$\lambda_{\text{violet}} \approx 2$	$1 \times 10^{-7} \text{ m}, \lambda_{\text{red}} \approx 7 \times 10^{-7} \text{ m}$ {N07P1Q34: need to recall these values}
	Power	of electromagnetic radiation, P = Rate of incidence of photon x Energy of a photon = $\binom{N}{t} \frac{hc}{\lambda}$
	FOWER	Si electromagnetic radiation, $T = Rate of mediance of photon x thereby of a photon = (t f \lambda)$
c.	Show a	in understanding that the photoelectric effect provides evidence for a particulate nature of
		magnetic radiation while phenomena such as interference and diffraction provide evidence
f.		ave nature. photoelectric phenomena in terms of photon energy and work function energy.
••	Explain	
		lectric effect refers to the <u>emission of electrons</u> from a cold <u>metal surface</u> when <u>electromagnetic</u> of <u>sufficiently high frequency</u> falls on it.
	<u>4 Major</u>	Observations:
	(a)	No electrons are emitted if the frequency of the light is below a minimum frequency {called the threshold frequency }, regardless of the intensity of light
	(b)	Rate of electron emission {ie photoelectric current} is proportional to the light intensity.
	(c)	{Emitted electrons have a range of kinetic energy, <u>ranging from zero to a certain maximum value</u> . Increasing the freq increases the kinetic energies of the emitted electrons and in particular, increases the maximum kinetic energy.} This <u>maximum</u> kinetic energy depends only on the frequency and the metal used { ϕ }; the intensity has no effect on the kinetic energy of the electrons.
	(d)	Emission of electrons begins instantaneously {i.e. no time lag between emission & illumination} even if the intensity is very low.
		NB: (a), (c) & (d) cannot be explained by Wave Theory of Light; instead they provide evidence for the particulate/particle nature of electromagnetic radiation.
		ation for how photoelectric effect provides evidence for the particulate nature of em
		$\frac{n}{2}$ (N07P3)
		er the observations (a), (c) & (d). Use <u>any 2</u> observations above to describe how they provide e that em radiation has a particle nature.}
	-	According to the "Particle Theory of Light", em radiation consists of a stream of particles/photons/discrete energy packets, each of energy hf. Also, no more than one electron can absorb the energy of one photon {" <u>All-or- Nothing Law</u> ".}
	-	Thus if the energy of a photon hf < the minimum energy required for emission (ϕ), no emission can take place no matter how intense the light may be. {E <i>xplains observation (a)</i> }
	-	This also explains why, { <i>even at very low intensities</i> }, as long as $hf > \phi$, emission takes place without a time delay between illumination of the metal & ejection of electrons.{ <i>Explains observation</i>

i.	Describe and interpret qualitatively the evidence provided by electron diffraction for the wave nature of particles.
j.	Recall and use the relation for the de Broglie wavelength $\lambda = \frac{n}{p}$.
	Wave-Particle Duality Concept
	- Refers to the idea that light and matter {such as electrons} have both wave & particle properties.
	- The wavelength of an object is given by $\lambda = \frac{h}{p} \{p: \text{momentum of the particle.}\}$
	- Interference and diffraction provide evidence for the wave nature of E.M. radiation.
	- <u>Photoelectric effect</u> provides evidence for the <u>particulate nature</u> of E.M. radiation.
	- These evidences led to the concept of the wave-particle duality of light.
	Electron diffraction provides evidence that matter /particles have also a wave nature & thus, have a dual nature.
	de Broglie wavelength of a particle {"matter waves"}, $\lambda = \frac{h}{p}$
k. I.	Show an understanding of the existence of discrete electron energy levels in isolated atoms (e.g. atomic hydrogen) and deduce how this leads to spectral lines. Recall and solve problems using the relation $hf = E_1 - E_2$.
	Energy Levels of Isolated Atom:
	 Are <u>discrete</u> {i.e. can only have certain energy values.}
	- Difference between successive energy levels ΔE : <u>decreases</u> as we move from ground state upwards.
	Explain how existence of electron energy levels in atoms gives rise to line spectra {N03P3Q6, 4 m}
	- Energy levels are discrete.
	- During a downward transition, a photon is emitted.
	- Freq of photon $f = \frac{E_i - E_f}{h}$
	 Since E_i & E_f can only have discrete values, the freq are also discrete and so a line {rather than a spectrum is produced. {No need to mention role of spectrometer}
	2 common ways to cause Excitation of an atom:
	- When bombarded by an incident <u>electron</u> where KE of incident electron > Δ E
	i.e. $(\frac{1}{2} m_e u^2)_{before \ collision} = \Delta E + (\frac{1}{2} m_e v^2)_{after \ collision}$
	- Absorbing an incident <u>photon</u> of frequency f where h f must = Δ E exactly
	The energy level of the ground state gives the ionization energy , i.e. the energy needed to <u>completely</u> removes an electron initially in the <u>ground state</u> from the atom {i.e. to the energy level $n = \infty$, where $E_{\infty} = 0$ }.
١.	Distinguish between emission and absorption line spectra.
	Emission line spectrum: A series of discrete/separate bright lines on a dark background, produced by electron transitions within an atom from higher to lower energy levels and emitting photons.
	An excited atom during a downward transition emits a photon of frequency f, such that $E_i - E_f = h f$

Absorption line spectrum: A continuous bright spectrum crossed by "dark" lines. It is produced when "white light" passes through a cool gas. Atoms/electrons of the cool gas absorb photons of certain frequencies and get excited to higher energy levels which are then quickly re-emitted in all directions. Explain the origins of the features of a typical X-ray spectrum using quantum theory. n. Characteristic X-rays: produced when an electron is knocked out of an inner shell of a target metal atom, allowing another electron from a higher energy level to drop down to fill the vacancy. The x-rays emitted have specific wavelengths, determined by the discrete energy levels which are characteristic of the target atom. Continuous X-ray Spectrum {Braking Radiation (Bremsstrahlung)}: produced when electrons are suddenly decelerated upon collision with atoms of the metal target. Minimum λ of cont. spectrum λ_{min} : given by $\frac{hc}{\lambda_{min}} = eV_a$, V_a : accelerating pd of x-ray tube Show an understanding of and apply the Heisenberg position-momentum and time-energy ο. uncertainty principles in new situations or to solve related problems. Heisenberg Uncertainty Principles: If a measurement of the position of a particle is made with uncertainty Δx and a simultaneous measurement of its momentum is made with uncertainty Δp , the product of these 2 uncertainties can never be smaller than $\frac{h}{4\pi}$ i.e. $\Delta x \Delta p \ge \frac{h}{4\pi}$ Similarly $\Delta E \Delta t \ge \frac{h}{4\pi}$ where E is the energy of a particle at time t Show an understanding that an electron can be described by a wave function ψ where the square of the amplitude of wave function $|\psi|^2$ gives the probability of finding the electron at a point. (No р. mathematical treatment is required.) A particle can be described by a wave function Ψ where the square of the amplitude of wave function, $|\Psi|^2$, is proportional to the probability of finding the particle at a point. Show an understanding of the concept of a potential barrier and explain qualitatively the q. phenomenon of quantum tunnelling of an electron across such a barrier. **Potential barrier** A region of electric field that prevents an atomic particle like an electron on one side of the barrier from passing through to the other side. OR A region where the potential energy of a particle, if it is placed there, is greater than the total energy of the particle. Hence the particle would experience an opposing force if it tries to enter into the potential barrier Describe the application of quantum tunnelling to the probing tip of a scanning tunnelling r. microscope (STM) and how this is used to obtain atomic-scale images of surfaces. (Details of the structure and operation of a scanning tunnelling microscope are not required.) Quantum tunnelling: A quantum-mechanical process whereby a particle penetrates a classically forbidden region of space, i.e. the particle goes through a potential barrier even though it does not have enough energy to overcome it. Due to the wave nature of a particle, there is a non-zero probability that the particle is able to penetrate the potential barrier. Scanning tunnelling microscope: Involves passing electrons from the tip of a probe through a potential barrier to a material that is to be

	scanned.				
	 <u>Quantum tunnelling</u> allows electrons to overcome the potential barrier between tip & material <u>Magnitude of tunnelling current is dependent on the dist betw the tip and the surface</u>. There are two methods to obtain images of the surface of the material: 				
	(1) Maintain the tip at constant height and measure the tunnelling current(2) Maintain a constant tunnelling current and measure the (vertical) position of the tip.				
	(A feedback device adjusts the vertical height of the tip to keep the tunnelling current const as the tip is scanned over the surface {Method 2}). The output of the device provides an image of the surface contour of the material.)				
s.		ionship transmission coefficient T \propto exp(–2kd) for the STM in related situations or to s. (Recall of the equation is not required.)			
	-	· · · · ·			
	Transmission	coefficient (T): measures the <u>probability</u> of a particle <u>tunnelling</u> through a barrier.			
		$k = \sqrt{\frac{8\pi^2 m(U - E)}{h^2}} $ {given in Formula List}			
	$T = e^{-2 k d}$	d: the thickness of the barrier in metres			
	I = e	m: mass of the tunnelling particle in kg			
		U: the "height" of the potential barrier <u>in J</u> {NOT: eV}			
		E: the energy of the electron in J h: The Planck's constant			
t.	Recall and us	e the relationship $R + T = 1$ where R is the reflection coefficient and T is the			
		oefficient, in related situations or to solve problems.			
	Reflection coe	fficient (R): measures the probability that a particle gets reflected by a barrier.			
		T + R = 1			

Cha	hapter 19: Lasers and Semiconductors						
	 Basic principles of lasers Energy bands, conductors and insulators 						
	- Semiconductors						
a.	- Depletion region of a p-n junction Recall and use the terms spontaneous emission, stimulated emission and population inversion in related situations.						
	Spontaneous emission:	A process whereby a photon is emitted when an electron in an excited atom falls <u>naturally</u> to a lower energy level, i.e. <u>without requiring an external event to trigger</u> <u>it.</u>					
	Stimulated emission:	A process whereby an <u>incoming photon</u> causes/induces another photon of the <u>same frequency & phase</u> (& direction) to be emitted from an excited atom.					
	Laser:	A monochromatic, coherent, parallel beam of high intensity light.					
	Meta stable state:	An excited state whose lifetime is much longer than the typical $(10^{-8} s)$ lifetime of excited states.					
	Population inversion:	A condition whereby there are more atoms in an excited state than in the ground state.					
		ssential for laser production because it is required for <u>population inversion</u> to be <u>ncreases the probability of stimulated emissions</u> .}					
b.		laser in terms of population inversion and stimulated emission. (Details of tion of a laser are not required.)					
	Conditions to achieve Laser action:						
	a. Atoms of the laser medium must have a meta-stable state.						
	b. The medium music.c. The emitted pho	tons must be confined in the system long enough to allow them to cause a chain lated emissions from other excited atoms.					
с.	Describe the formation of energy bands in a solid.						
	Formation of Energy Bands in a Solid/Band theory for solids:						
	- Unlike the case of an <i>isolated atom</i> , in a <i>solid</i> , the atoms are <u>very much closer</u> to each other.						
	- This allows the electrons from neighbouring atoms to interact with each other.						
	 As a result of this interaction, each discrete energy level that is associated with an isolated atom is <u>split</u> into many sub-levels. {<i>This is in accordance to Pauli Exclusion Principle which states that: no 2 electrons can be in the same energy state</i>} 						
	- These sub-levels are <u>extremely close</u> to one another such that they form an <u>energy band</u> . {In other words, an energy band consists of a very large number of energy levels which are very close together.}						
d.	Distinguish between conduction band and valence band.						
	Valence Band: The <u>highest</u> energy band that is <u>completely</u> filled with electrons.						
	Conduction Band:	The <u>next higher</u> band; For some metals/ good conductors, it is <u>partially-filled;</u> For other metals, the VB & CB <u>overlap</u> {hence it is also <u>partially-filled</u> }					
	Energy Gap {Forbidden Band}A region where no energy state can exist; It is the energy difference between the CB & VB

d.	Use the usual notation for the representation of nuclides and represent simple nuclear reactions by nuclear equations of the form $\frac{14}{7}$ N + $\frac{4}{2}$ He $\rightarrow \frac{17}{8}$ O + $\frac{1}{1}$ H.
	Self-Explanatory
e. f.	Show an understanding of the concept of mass defect. Recall and apply the equivalence relationship between energy and mass as represented by $E = mc^2$ in problem solving.
g. i.	Show an understanding of the concept of binding energy and its relation to mass defect. Explain the relevance of binding energy per nucleon to nuclear fusion and to nuclear fission.
	Energy & Mass are Equivalent: $E = mc^2 \rightarrow \Delta E = (\Delta m)c^2$
	Nuclear Binding Energy:
	 Energy that must be supplied to completely separate the nucleus into its individual nucleons/particles.
	OR
	- The energy released {not <i>lost</i> } when a nucleus is formed from its constituent nucleons.
	B.E. per nucleon is a measure of the <u>stability</u> of the nucleus.
	Mass Defect : The difference in mass between a nucleus and the total mass of its individual nucleons = Zm_p + (A-Z) m_n – Mass of Nucleus
	Thus, Binding Energy. = Mass Defect × c ²
	In both nuclear fusion and fission, products have <u>higher</u> B.E. per nucleon {due to shape of BE per nucleon-nucleon graph}, energy is released {not <i>lost</i> } and hence products are <u>more stable</u> .
	Energy released = Total B.E. after reaction (of products) - Total B.E. before reaction (ie of reactants)
	Nuclear fission: The disintegration of a heavy nucleus into 2 lighter nuclei. Typically, the fission fragments have approximately the <u>same mass</u> and <u>neutrons are emitted</u> .
h.	Sketch the variation of binding energy per nucleon with nucleon number.
	Fig below shows the variation of BE per nucleon plotted against the nucleon no.

S.	5. Discuss qualitatively the effects, both direct and indirect, of ionising radiation on living tissues and cells.					
	Radiation damage to biological organisms is often categorized as: somatic and genetic.					
	<u>Somatic damage</u> refers to any part of the body except the reproductive organs. Somatic damage <u>harms that particular organism</u> <u>directly</u> . Some somatic effects include radiation sickness (nausea, fatigue, and loss of body hair) and burns, reddening of the skin, ulceration, cataracts in the eye, skin cancer, leukaemia, reduction of white blood cells, death, etc.					
	<u>Genetic damage</u> refers to damage to reproductive organs. Genetic effects cause <u>mutations</u> in the reproductive cells and so affect <u>future generations</u> – hence, their effects are <u>indirect</u> . (Such mutations may contribute to the formation of a cancer.)					
	Alternatively,					
	- Ionising radiation may damage living tissues and cells <u>directly</u> .					
	- It may also occur <u>indirectly</u> through chemical changes in the surrounding medium, which is mainly water. For example, the ionization of water molecules produces OH free radicals which may react to produce H ₂ O ₂ , the powerful oxidizing agent hydrogen peroxide, which can then attack the molecules which form the chromosomes in the nucleus of each cell.
